ABSTRACT: New physics can manifest itself by an appreciable increase of the decay rate of top quarks in rare flavour-changing final states. Exploiting the large top quark production rate at the LHC, we bound four-fermion operators contributing to non-resonant $t \rightarrow \ell^+ \ell^- j$ using different signal regions of the latest LHC searches for $t \rightarrow Zj$. We also provide prospects for the high-luminosity LHC to test these as well as four-fermion operators contributing to $t \rightarrow b\bar{b}j$, based on improved analysis strategies of existing searches. We single out all weakly-coupled ultraviolet completions inducing such contact interactions at tree level and translate the previous bounds to the parameter space of specific complete models. Being above the TeV, LHC bounds from rare top decays improve over those from flavour physics, electroweak precision data and other LHC searches in several cases.

1 Introduction

The very good agreement between the Standard Model (SM) predictions and the current data suggests that new physics might only lie at energies significantly above the electroweak (EW) scale. If this is true, its effects could be therefore accurately captured by a set of SM effective operators. One such independent operator exists at dimension five [1], whereas 59 independent operators up to flavour indices appear at dimension six [2, 3]. Numerous studies have been performed with the aim of constraining the SM Effective Field Theory (SMEFT); see e.g. refs. [4–9] for recent analyses.

The operators with largest coefficients are expected to be those which can be induced at tree level in UV completions of the SM [10]. Among them, we find in particular four-fermion operators. Studies of four-light-quark operators at the LHC can be found in ref. [11]. Analyses of different types of four-lepton operators can be obtained in refs. [7, 12–15]. Likewise, bounds on two-light-quark-two-lepton operators using low-energy as well as LHC data have been obtained in refs. [14, 16–20]. Searches for two-top-two-light-quark operators in top single and pair production have been worked out in refs. [21]. Ref. [22] provided limits on four-top and two-top-two-lepton operators from their effects on EW Precision Data (EWPD) from Renormalization Group Evolution (RGE); see also refs. [7, 23]. Studies of four-top operators have been also considered in four-top production [24] and top pair-production in association with b quarks [24–26]. However, four-fermion operators involving one top as well as light quarks and/or leptons have received only little attention [21, 27–30], despite appearing in several scenarios of new physics. In fact, no dedicated LHC search for these interactions has been developed. Analyses devoted for other experimental signatures might be sensitive to rare top decays mediated by four-fermion operators, though. Thus, in this article we consider the latest and most constraining search for $t \rightarrow Zj$ to date [31], and demonstrate that it can already constrain the scale of contact interactions contributing to

non-resonant $t \rightarrow \ell^+ \ell^- j$ beyond the TeV. This possibility has been previously pointed out in the literature; see e.g. refs. [27, 29]. However, actual limits on four-fermion interactions using existing searches for $t \rightarrow Zj$ have not been reported. Moreover, the reach of dedicated analyses for testing these operators at the LHC has not been estimated, which we intend to rectify. Thus, we also design new analyses to test four-fermion operators contributing to non-resonant $t \rightarrow b\bar{b}j$.

The reason for focusing on rare top decays is primarily motivated by the fact that top quarks are copiously produced at the LHC. Further, several contact-interactions, like those giving only $\sim t c \mu^+ \mu^-$ can not be directly probed otherwise.

This paper is organized as follows. In section 2 we describe first the set of effective interactions we are interested in. We then focus on those contributing to $t \rightarrow \ell^+ \ell^- j$. We recast the latest and most constraining search for $t \rightarrow Zj$ and provide bounds on the coefficients of such contact interactions. We also estimate the reach of modified versions of this analysis to constrain contact-interactions in the High-Luminosity LHC (HL-LHC) phase, defined by $\sqrt{s} = 14 \text{ TeV}$ and $\mathcal{L} = 3 \text{ ab}^{-1}$. We subsequently focus on the $t \rightarrow b\bar{b}j$ channel, for which dedicated searches have not been performed yet. We also comment briefly on the reach of other facilities to the contact-interactions we bound in this article in comparison with our findings. These include measurements of $b \rightarrow s \mu^+ \mu^-$, $B_s - \bar{B}_s$ mixing, the B_c^- lifetime, EWPD and the cross section of single-top production.

We extend the previous results to operators involving tau leptons as well as lepton-flavour violation (LFV) in section 3. We compare the sensitivity of our analyses with the one achieved by low energy experiments such as $\mu^\pm \rightarrow e^\pm \gamma$, $\mu^\pm \rightarrow e^\pm e^\mp e^\pm$ and the tau counterparts. In section 4 we provide the list of all possible weakly-coupled UV completions inducing the four-fermion operators of interest at tree level. We demonstrate that wide regions of their parameter spaces can be better bounded by searches for anomalous top decays than by other experiments. Finally, we conclude in section 5.

2 Framework

The only four-fermion operators contributing to $t \rightarrow \ell^+ \ell^- j$ are linear combinations of

$$\mathcal{O}_{lq}^{-(ijkl)} = \frac{1}{2} [\bar{l}_L^i \gamma^\mu l_L^j] (\bar{q}_L^k \gamma_\mu q_L^l) - (\bar{l}_L^i \gamma^\mu \sigma^I l_L^j) (\bar{q}_L^k \gamma_\mu \sigma_I q_L^l), \quad \mathcal{O}_{eq}^{(ijkl)} = (\bar{e}_R^i \gamma^\mu e_R^j) (\bar{q}_L^k \gamma_\mu q_L^l), \quad (2.1)$$

$$\mathcal{O}_{lu}^{(ijkl)} = (\bar{l}_L^i \gamma^\mu l_L^j) (\bar{u}_R^k \gamma_\mu u_R^l), \quad \mathcal{O}_{eu}^{(ijkl)} = (\bar{e}_L^i \gamma^\mu e_L^j) (\bar{u}_R^k \gamma_\mu u_R^l), \quad (2.2)$$

$$\mathcal{O}_{lequ}^{1(ijkl)} = (\bar{l}_L^i e_R^j) \varepsilon (\bar{q}_L^k u_R^l), \quad \mathcal{O}_{lequ}^{3(ijkl)} = (\bar{l}_L^i \sigma_{\mu\nu} e_R^j) \varepsilon (\bar{q}_L^k \sigma^{\mu\nu} u_R^l), \quad (2.3)$$

where i, j, k, l are flavour indices (one of the quark flavour indices will correspond to the third generation and the other to one of the first two), σ^I are the Pauli matrices and $\varepsilon \equiv i\sigma^2$.

Analogously, in the four-quark sector we consider the following set of linearly-independent operators:

$$\mathcal{O}_{qq}^{1(ijkl)} = (\overline{q_L^i} \gamma^\mu q_L^j) (\overline{q_L^k} \gamma_\mu q_L^l), \quad \mathcal{O}_{qq}^{3(ijkl)} = (\overline{q_L^i} \sigma^I \gamma^\mu q_L^j) (\overline{q_L^k} \sigma_I \gamma_\mu q_L^l), \quad (2.4)$$

$$\mathcal{O}_{qu}^{1(ijkl)} = (\overline{q_L^i} \gamma^\mu q_L^j) (\overline{u_R^k} \gamma_\mu u_R^l), \quad \mathcal{O}_{qu}^{8(ijkl)} = (\overline{q_L^i} T^A \gamma^\mu q_L^j) (\overline{u_R^k} T_A \gamma_\mu u_R^l), \quad (2.5)$$

$$\mathcal{O}_{qd}^{1(ijkl)} = (\overline{q_L^i} \gamma^\mu q_L^j) (\overline{d_R^k} \gamma_\mu d_R^l), \quad \mathcal{O}_{qd}^{8(ijkl)} = (\overline{q_L^i} T^A \gamma^\mu q_L^j) (\overline{d_R^k} T_A \gamma_\mu d_R^l), \quad (2.6)$$

$$\mathcal{O}_{ud}^{1(ijkl)} = (\overline{u_R^i} \gamma^\mu u_R^j) (\overline{d_R^k} \gamma_\mu d_R^l), \quad \mathcal{O}_{ud}^{8(ijkl)} = (\overline{u_R^i} T^A \gamma^\mu u_R^j) (\overline{d_R^k} T_A \gamma_\mu d_R^l), \quad (2.7)$$

$$\mathcal{O}_{quqd}^{1(ijkl)} = (\overline{q_L^i} u_R^j) \varepsilon (\overline{q_L^k}^T d_R^l), \quad \mathcal{O}_{quqd}^{8(ijkl)} = (\overline{q_L^i} T^A u_R^j) \varepsilon (\overline{q_L^k}^T T_A d_R^l). \quad (2.8)$$

where $T_A = \lambda^A/2$ with λ^A the Gell-Mann matrices.

When giving specific numerical results in this section we will consider the case $j = c, \ell^\pm = \mu^\pm$. Implications of departures from this assumption will be discussed in section 3.

2.1 Results for $t \rightarrow \ell^+ \ell^- j$

The relevant effective Lagrangian is given by

$$\begin{aligned} \mathcal{L} = \frac{1}{\Lambda^2} & \left[c_{lq}^{-(ijkl)} \mathcal{O}_{lq}^{-(ijkl)} + c_{eq}^{(ijkl)} \mathcal{O}_{eq}^{(ijkl)} + c_{lu}^{(ijkl)} \mathcal{O}_{lu}^{(ijkl)} + c_{eu}^{(ijkl)} \mathcal{O}_{eu}^{(ijkl)} \right. \\ & \left. + \left\{ c_{lequ}^{1(ijkl)} \mathcal{O}_{lequ}^{1(ijkl)} + c_{lequ}^{3(ijkl)} \mathcal{O}_{lequ}^{3(ijkl)} + \text{h.c.} \right\} \right]. \end{aligned} \quad (2.9)$$

The decay width of the top quark from this effective Lagrangian was computed in ref. [21] in a different basis. Translating it to our operator basis we get

$$\begin{aligned} \Gamma(t \rightarrow \ell_i^+ \ell_j^- u_k) = \frac{m_t}{6144\pi^3} \left(\frac{m_t}{\Lambda} \right)^4 & \left\{ 4|c_{lq}^{-(jik3)}|^2 + 4|c_{eq}^{(jik3)}|^2 + 4|c_{lu}^{(jik3)}|^2 + 4|c_{eu}^{(jik3)}|^2 \right. \\ & \left. + |c_{lequ}^{1(jik3)}|^2 + |c_{lequ}^{1(ij3k)}|^2 + 48|c_{lequ}^{3(jik3)}|^2 + 48|c_{lequ}^{3(ij3k)}|^2 \right\}. \end{aligned} \quad (2.10)$$

Since we are only sensitive to the absolute value of the Wilson coefficients, we assume in the following that they are real. In particular this implies that

$$c_{lq}^{-(jilk)} = c_{lq}^{-(ijkl)}, \quad c_{eq}^{(jilk)} = c_{eq}^{(ijkl)}, \quad c_{lu}^{(jilk)} = c_{lu}^{(ijkl)}, \quad c_{eu}^{(jilk)} = c_{eu}^{(ijkl)}, \quad (2.11)$$

We note that

$$\begin{aligned} \sigma(pp \rightarrow t\bar{t}, t(\bar{t}) \rightarrow \ell^+ \ell^- j, \bar{t}(t) \rightarrow \text{all}) & = 2 \times \sigma(pp \rightarrow t\bar{t}) \times \mathcal{B}(t \rightarrow \ell^+ \ell^- j) \\ & = 2 \times \sigma(pp \rightarrow t\bar{t}) \times \frac{\Gamma(t \rightarrow \ell^+ \ell^- j)}{\Gamma_t}, \end{aligned} \quad (2.12)$$

where the top quark's total width is $\Gamma_t \sim 1.35$ GeV and $\sigma(pp \rightarrow t\bar{t}) \sim 830$ pb at NNLO [32]. Using the production cross section in terms of the partial width and the fact that the number of events in a certain signal region of an analysis is given by

$$s = \sigma \times \epsilon \times \mathcal{L}, \quad (2.13)$$

where ϵ is the efficiency for the signal in the corresponding region and \mathcal{L} the integrated luminosity used in the analysis, we can write a master equation for the observed number of signal events in specific regions of parameter space:

$$\begin{aligned}
 s(t \rightarrow \ell_i^+ \ell_j^- u_k) = & \frac{1}{\Lambda^4} \left[\alpha_{lq}^{-(jik3)} |c_{lq}^{-(jik3)}|^2 + \alpha_{eq}^{(jik3)} |c_{eq}^{(jik3)}|^2 \right. \\
 & + \alpha_{lu}^{(jik3)} |c_{lu}^{(jik3)}|^2 + \alpha_{eu}^{(jik3)} |c_{eu}^{(jik3)}|^2 \\
 & + \alpha_{lequ}^{1(jik3)} |c_{lequ}^{1(jik3)}|^2 + \alpha_{lequ}^{1(ij3k)} |c_{lequ}^{1(ij3k)}|^2 \\
 & \left. + \alpha_{lequ}^{3(jik3)} |c_{lequ}^{3(jik3)}|^2 + \alpha_{lequ}^{3(ij3k)} |c_{lequ}^{3(ij3k)}|^2 \right], \quad (2.14)
 \end{aligned}$$

where the different α encode the efficiencies of the particular analysis for each contribution.

The LHC has the largest sensitivity to several of the four-fermions operators above [27]. However, no dedicated analysis in this respect has been worked out yet. Among the most constraining analyses we find therefore searches for $t \rightarrow Zj$, mediated by operators such as $\mathcal{O}_{uB}^{(ij)} = (\bar{q}_L^i \sigma^{\mu\nu} u_R^j) \tilde{\varphi} B_{\mu\nu}$, with φ the Higgs doublet. Although the leptons resulting from the top decay via the contact interactions do not always reconstruct a Z boson, we will show that these kind of searches do still have a large sensitivity. To this end, we consider the latest ATLAS search [31] for FCNC top quark decays at LHC13, i.e. $\sqrt{s} = 13$ TeV and $\mathcal{L} = 36 \text{ fb}^{-1}$. It provides the strongest limit on $\mathcal{B}(t \rightarrow Zj)$ to date. In short terms, this analysis demands three light leptons (either electrons or muons), two of them same-flavour opposite-sign (SFOS), as well as exactly one b -tagged jet and at least two more light jets. (The b -tagging efficiency is reported to be 0.77, while the misstag rates $\mathcal{P}(c \rightarrow b)$ and $\mathcal{P}(j \rightarrow b)$ are 0.16 and 0.0075 respectively [31].)

The two SFOS leptons whose invariant mass $m_{\ell^+\ell^-}$ is closest to the Z pole are considered as the Z boson candidate. We notice that most events peak at invariant masses very different from the Z mass in the non-resonantly produced signal. However, a sizeable fraction of the events still populate the Z peak despite the leptons being produced from effective operators rather than from the decay of the Z . This result is explicitly shown in the left panel of figure 1, where the distribution of $m_{\ell^+\ell^-}$ after the basic cuts of the experimental analysis is depicted. Moreover, the total transverse missing energy is forced to be $E_T^{\text{miss}} > 20$ GeV.

On top of the observables above, the analysis considers the invariant masses $m_{\ell^+\ell^-j}$, $m_{\ell^\pm b\nu}$ and $m_{\ell^\pm\nu}$, where ℓ^\pm refers to the non- Z lepton, b is the b -tagged jet and ν the neutrino. The momentum of the latter, as well as the momentum of the selected jet j are those minimizing

$$\chi^2 = \frac{(m_{\ell^+\ell^-j} - m_{t_{\text{FCNC}}})^2}{\sigma_{t_{\text{FCNC}}}^2} + \frac{(m_{\ell^\pm b\nu} - m_{t_{\text{SM}}})^2}{\sigma_{t_{\text{SM}}}} + \frac{(m_{\ell^\pm\nu} - m_W)^2}{\sigma_W}, \quad (2.15)$$

with $m_{t_{\text{FCNC}}} = 169.6$ GeV, $m_{t_{\text{SM}}} = 167.2$ GeV, $m_W = 81.2$ GeV, $\sigma_{t_{\text{FCNC}}} = 12.0$ GeV, $\sigma_{t_{\text{SM}}} = 24.0$ GeV and $\sigma_W = 15.1$ GeV. These variables behave almost equally in the $t \rightarrow Zj$ and the contact-interaction cases; see an example in the right panel of figure 1.

Two regions of interest for our analysis are studied in the experimental paper. First, the signal region SRA. It requires $m_{\ell^+\ell^-}$ to be within the range [76.2, 106.2] GeV. It further

Table 1. Coefficients of the master equation (2.14), in TeV^4 , for the different signal regions and for LHC13. In the HL-LHC, the coefficients should be multiplied by a factor 100 to account for the increase in production cross section and luminosity. See text for the definition of the different signal regions.

imposes $|m_{\ell+\ell-j} - 172.5| < 40 \text{ GeV}$, $|m_{\ell\pm b\nu} - 172.5| < 40 \text{ GeV}$ and $|m_{\ell\pm\nu} - 80.4| < 30 \text{ GeV}$. We use this region to validate our simulations. Given the numbers in table 8 of the experimental reference, one can conclude that the efficiency for selecting $t\bar{t}$ events with one of the top decaying as $t \rightarrow Zc$ is about 2.4%.

We have recast the corresponding cuts using home-made routines based on ROOT v6 [33] and Fastjet v3 [34]. We have applied them to Monte Carlo events generated using MadGraph v5 [35] with the UFO model [36] of ref. [37]. We have further used Pythia v6 [38] to simulate radiation, fragmentation and hadronization processes. The efficiency we obtain matches very well that previously reported.

Another region of interest, not used in the experimental analysis to bound new physics but rather to validate the non-prompt lepton backgrounds, is the one dubbed CR1 [31]. On top of the basic cuts, it also requires $|m_{\ell+\ell-} - 91.2| > 15 \text{ GeV}$, being therefore more sensitive to four-fermion operators. It does not cut on $m_{\ell+\ell-j}$, $m_{\ell\pm b\nu}$ or $m_{\ell\pm\nu}$. We have computed the corresponding efficiencies, obtaining values ~ 0.015 . This results in the coefficients of the master equation shown in the first row of table 1. The experimental collaboration reports the observation of 260 observed events, while 230 ± 70 are predicted. Using the CL_s method [39], we determine the maximum number of signal events allowed at the 95 % CL including the $\sim 30\%$ systematic uncertainty on the SM prediction, obtaining $s_{\text{max}} = 143$. Our master equation then allows us to set limits on arbitrary combinations of the coefficients of the four-fermion operators. Assuming for simplicity one operator at a time these bounds are shown, for $\Lambda = 1 \text{ TeV}$, in boldface in the first row of table 2.

Table 2. Bounds on c for $\Lambda = 1$ TeV, assuming one operator at a time, using the different signal regions defined in the text. The numbers without (within) parenthesis stand for the LHC13 (HL-LHC). The boldface indicates limits using actual data. These numbers can be obtained from the master equation (2.14) using the coefficients in table 1 and the upper bound on the following number of signal events: $s_{\max}^{\text{CR1}} = 143$ (315) and $s_{\max}^{\text{NEW}} = 18$ (179), where again the number in brackets correspond to HL-LHC projections. The projected bounds on the coefficients get a factor of ~ 3 weaker for systematic uncertainties of 10%.

We also provide naive prospects for the HL-LHC. For this aim, we scale the background cross section by a conservative factor of 1.3. This number corresponds to the enhancement in cross section for $t\bar{t}Z$ from $\sqrt{s} = 13$ TeV to $\sqrt{s} = 14$ TeV, being the largest among the dominant backgrounds. For the signal, we assume an enhancement of ~ 1.2 [32]. We further scale the number of events with the ratio of luminosities, $\sim 3 \text{ ab}^{-1}/36 \text{ fb}^{-1} \sim 83$. Assuming the number of observed events equal to the number of SM events, we find that $s_{\max} = 315$. (This number becomes an order of magnitude larger for systematic uncertainties of 10%.) Projected bounds on the operator coefficients are also shown, within parentheses, in the first row of table 2.

We can improve further these bounds by extending CR1 with the cuts on $m_{\ell^+\ell^-j}$, $m_{\ell^\pm b\nu}$ and $m_{\ell^\pm\nu}$ required in SRA. Such a new sharpened signal region has not been yet considered experimentally. Therefore, we estimate the number of expected SM events from simulation. To this end, we first check our Monte Carlo for the background comparing the expectations for CR1 with those reported in the experimental analysis. This region is dominated, first, by non-prompt leptons (coming mainly from $t\bar{t}$). We get an efficiency of selecting events in the CR1 region of ~ 0.04 . Fixing the misstag rate $\mathcal{P}(j \rightarrow e^\pm) = 3 \times 10^{-4}$ (which is well within the actual range; see e.g. ref. [40]), we match the number of events reported in table 5 of ref. [31]: 140 (± 70). We find good agreement in the other backgrounds too, with the exception of WZ for which we have much less events than provided in the paper. Still, being subdominant, and given the large error reported by ATLAS in the determination of that background, we proceed without this sample. Around ~ 73 background events survive in this new region for $\mathcal{L} = 36 \text{ fb}^{-1}$. Assuming the observation of only background events and no systematic uncertainties, we get $s_{\max} \sim 18$ (~ 179 for the HL-LHC). These numbers get a factor of ~ 1.2 (~ 10) larger with 10% systematics. The signal efficiencies are in this case of about ~ 0.013 . The corresponding coefficients for the master equation are given in the second row of table 1. Using these numbers, we obtain the limits as before and show them in the last row on table 2. Being non-boldface, we emphasize again that they are not actual limits but potential ones.

We note that scales as large as ~ 1 TeV for $\mathcal{O}(1)$ couplings are already bounded in some cases. The best limits at the HL-LHC will probe scales of the order of $\Lambda \sim 2$ (3.5) TeV for $c \sim 1$ ($\sqrt{4\pi}$). Bounds from flavour physics are more stringent for operators

involving Left-Handed (LH) quarks, whereas they are irrelevant for Right-Handed (RH) ones. Indeed, in the former case $b \rightarrow s\mu^+\mu^-$ transitions arise at tree level. They modify the $\mathcal{B}(B_s \rightarrow \mu^+\mu^-)$ by an amount of $\sim g_2^4/(16\pi\Lambda^4)f_B^2m_\mu^2m_B/\Gamma_B$, with g_2 the $SU(2)_L$ gauge coupling, $f_B \sim 0.2\text{ GeV}$, $m_B \sim 5\text{ GeV}$ and $\Gamma_B \sim 4 \times 10^{-13}$ [41]. Therefore, for $\Lambda = 1\text{ TeV}$, $\mathcal{B}(B_s \rightarrow \mu^+\mu^-) \sim 6 \times 10^{-6}$, orders of magnitude larger than the measured value $(2.8_{-0.6}^{+0.7}) \times 10^{-9}$ [42].

However, the contribution of operators such as $\mathcal{O}_{eu}^{(2223)}$ is chirality and loop suppressed, being therefore further reduced by a factor of $\sim N_c^2g_2^4/(16\pi^2)^2m_c^2/v^2 \sim 10^{-10}$ and hence negligible. The decay of the vector meson $B_s^* \rightarrow \mu^+\mu^-$ could be much larger because it is not helicity suppressed [43, 44]. However, to the date there are no direct measurements of this observable.

2.2 Results for $t \rightarrow b\bar{b}j$

The relevant Lagrangian reads for this case

$$\begin{aligned} \mathcal{L} = \frac{1}{\Lambda^2} & \left[c_{qq}^{1(ijkl)} \mathcal{O}_{qq}^{1(ijkl)} + c_{qq}^{3(ijkl)} \mathcal{O}_{qq}^{3(ijkl)} + c_{qu}^{1(ijkl)} \mathcal{O}_{qu}^{1(ijkl)} + c_{qu}^{8(ijkl)} \mathcal{O}_{qu}^{8(ijkl)} \right. \\ & + c_{qd}^{1(ijkl)} \mathcal{O}_{qd}^{1(ijkl)} + c_{qd}^{8(ijkl)} \mathcal{O}_{qd}^{8(ijkl)} + c_{ud}^{1(ijkl)} \mathcal{O}_{ud}^{1(ijkl)} + c_{ud}^{8(ijkl)} \mathcal{O}_{ud}^{8(ijkl)} \\ & \left. + \left\{ c_{quqd}^{1(ijkl)} \mathcal{O}_{ququ}^{1(ijkl)} + c_{quqd}^{8(ijkl)} \mathcal{O}_{ququ}^{8(ijkl)} + \text{h.c.} \right\} \right]. \end{aligned} \quad (2.16)$$

These operators alter the width of $\Gamma(t \rightarrow b\bar{b}j)$ at the level of $1/\Lambda^4$. The only exceptions are the LL operators, which interfere with the SM. However, the interference is suppressed by a factor of $\sim V_{12}^{\text{CKM}}/100$; see eq. (21) in ref. [21], and we will neglect it in the rest of this article. Translating the results of [21] to our basis we obtain the following expression for the decay width:

$$\begin{aligned} \Gamma(t \rightarrow b\bar{b}u_i) = \frac{m_t}{2048\pi^3} \left(\frac{m_t}{\Lambda} \right)^4 & \left\{ 4 \left[|c_{qq}^{1(33i3)}|^2 + |c_{qu}^{1(33i3)}|^2 + |c_{qd}^{1(i333)}|^2 + |c_{ud}^{1(i333)}|^2 \right] \right. \\ & + \frac{8}{9} \left[\frac{33}{2} |c_{qq}^{3(33i3)}|^2 + |c_{qu}^{8(33i3)}|^2 + |c_{qd}^{8(i333)}|^2 + |c_{ud}^{8(i333)}|^2 \right] \\ & - \frac{8}{3} \text{Re} \left[(c_{qq}^{1(33i3)})(c_{qq}^{3(33i3)})^* \right] \\ & + |c_{quqd}^{1(i333)}|^2 + |c_{quqd}^{1(33i3)}|^2 + \frac{7}{3} |c_{quqd}^{1(3i33)}|^2 \\ & + \frac{2}{9} (|c_{quqd}^{8(i333)}|^2 + |c_{quqd}^{8(33i3)}|^2) + \frac{10}{27} |c_{quqd}^{8(3i33)}|^2 \\ & + \frac{1}{3} \text{Re} \left[(c_{quqd}^{1(i333)})(c_{quqd}^{1(33i3)})^* \right] - \frac{2}{27} \text{Re} \left[(c_{quqd}^{8(i333)})(c_{quqd}^{8(33i3)})^* \right] \\ & + \frac{4}{9} \text{Re} \left[(c_{quqd}^{1(i333)})(c_{quqd}^{8(33i3)})^* \right] + \frac{4}{9} \text{Re} \left[(c_{quqd}^{8(i333)})(c_{quqd}^{1(33i3)})^* \right] \\ & \left. + \frac{8}{9} \text{Re} \left[(c_{quqd}^{1(3i33)})(c_{quqd}^{8(3i33)})^* \right] \right\}. \end{aligned} \quad (2.17)$$

Using this expression and the equivalent of eq. (2.12) for the hadronic case and eq. (2.13) we can write a master equation for the number of signal events

$$s(t \rightarrow b\bar{b}u_i) = \frac{1}{\Lambda^4} \vec{\alpha}_{bbu_i} \cdot \vec{c}_{bbu_i}, \quad (2.18)$$

where

$$\begin{aligned} \vec{c}_{bbu_i} \equiv & (|c_{qq}^{1(33i3)}|^2, |c_{qu}^{1(33i3)}|^2, |c_{qd}^{1(i333)}|^2, |c_{ud}^{1(i333)}|^2, |c_{qq}^{3(33i3)}|^2, |c_{qu}^{8(33i3)}|^2, |c_{qd}^{8(i333)}|^2, |c_{ud}^{8(i333)}|^2, \\ & \text{Re} \left[(c_{qq}^{1(33i3)})(c_{qq}^{3(33i3)})^* \right], |c_{quqd}^{1(i333)}|^2, |c_{quqd}^{1(33i3)}|^2, |c_{quqd}^{1(3i33)}|^2, |c_{quqd}^{8(i333)}|^2, |c_{quqd}^{8(33i3)}|^2, |c_{quqd}^{8(3i33)}|^2, \\ & \text{Re} \left[(c_{quqd}^{1(i333)})(c_{quqd}^{1(33i3)})^* \right], \text{Re} \left[(c_{quqd}^{8(i333)})(c_{quqd}^{8(33i3)})^* \right], \text{Re} \left[(c_{quqd}^{1(i333)})(c_{quqd}^{8(33i3)})^* \right], \\ & \text{Re} \left[(c_{quqd}^{8(i333)})(c_{quqd}^{1(33i3)})^* \right], \text{Re} \left[(c_{quqd}^{1(3i33)})(c_{quqd}^{8(3i33)})^* \right])^T \end{aligned} \quad (2.19)$$

No experimental analysis tagging the top decay into $b\bar{b}j$ sensitive to four-fermion operators has been worked out to the date. We demonstrate, however, that a sensible reach can be obtained in the HL-LHC. To this end, we follow closely the analysis of ref. [45]. Both muons and electrons are defined by $p_T^\ell > 10$ GeV and $|\eta_\ell| < 2.5$. Jets are clustered using the anti- k_T algorithm with $R = 0.4$ and they are required to have $p_T^j > 30$ GeV and $|\eta_j| < 2.5$. We require the presence of exactly one isolated lepton and four jets, of which exactly three must be b -tagged. The b -tagging efficiency has been fixed to 0.7; the charm (light jet) mistag rate being 0.1 (0.01). We will refer to this set of cuts as *basic cuts* hereafter. We then obtain the two b -tagged jets closest in ΔR , out of which we reconstruct the hadronic top mass $m_t^{\Delta R}$ by joining their momenta with that of the light jet. Out of the lepton, the third b -jet and the missing energy, we also construct the transverse mass m_T . We require $|m_t^{\Delta R} - 175| < 50$ GeV as well as $m_T < 200$ GeV. Finally, we construct the invariant mass of the third b -tagged jet and the light one, $m_{b_{3j}}$. This usually peaks around the W boson mass in the background; see figure 2. We thus enforce $m_{b_{3j}} > 80$ GeV. The main background ensues from $t\bar{t}$ (including the CKM suppressed $t \rightarrow bW, W \rightarrow bc$) merged up to one extra hard jet as well as from $t\bar{t}b\bar{b}$, both in the semi-leptonic (SL) and di-Leptonic (LL) channels. We also include the leptonic $Wb\bar{b}$ and $Zb\bar{b}$ merged up to two extra matrix element partons. For the matching procedure, we employ the MLM merging scheme [46]. The cross sections for $t\bar{t}b\bar{b}$, $t\bar{t}$, $Wb\bar{b}$ and $Zb\bar{b}$ are multiplied by the QCD NLO K -factors of 1.13, 1.6, 2.3 and 1.25, respectively [32, 47]. For both the signal and the background, we use the NNPDF 2.3 [48] at leading order.

The cutflow is shown in table 3. The efficiency of selecting signal events (with one top decaying exotic) is operator independent to very good accuracy; being roughly $\sim 3.6 \times 10^{-3}$. This results in the coefficients for the master equation, eq. (2.18), shown in table 4. The total number of background events is of order $\sim 3 \times 10^5$. Therefore, using again the CL_s method we obtain $s_{\text{max}} \sim 1.1 \times 10^3$ (6×10^4) under the assumption of no systematic uncertainties (10% systematics). This corresponds to a 95% CL exclusion $\mathcal{B}(t \rightarrow b\bar{b}j) > 5.9 \times 10^{-5}$ (3×10^{-3}) at the HL-LHC. Using eq. (2.18) with the coefficients in table 4 we obtain, for the particular case of one operator at a time, the bounds in table 5. The bounds on each operator, computed after marginalizing over all operators interfering with it, become at most 10% weaker.

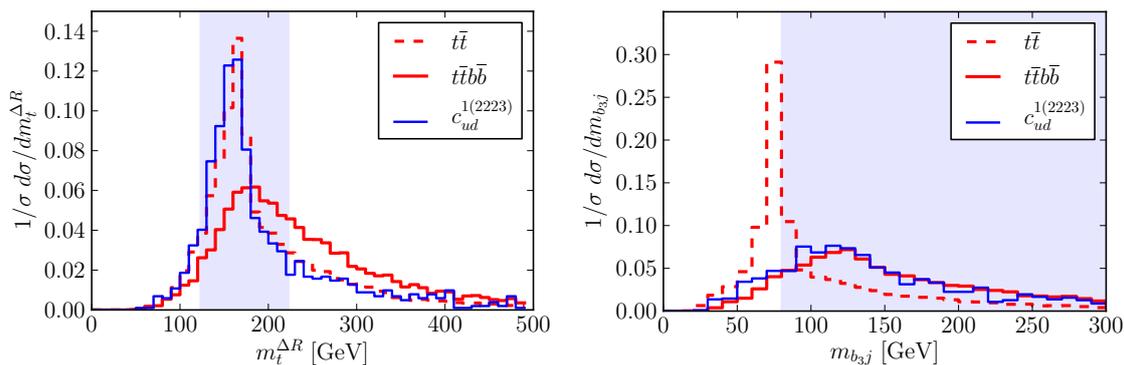

Figure 2. Normalized distributions of $m_t^{\Delta R}$ (left) and $m_{b_{3j}}$ (right) in the signal (thin solid blue) and the two main backgrounds: $t\bar{t}$ (thin dashed red) and $t\bar{t}b\bar{b}$ (thick solid red). The cut imposed in our analysis is represented by the blue shaded area.

Cuts	$t\bar{t}$ (SL)	$t\bar{t}$ (LL)	$Wb\bar{b}$	$Zb\bar{b}$	$t\bar{t}b\bar{b}$ (SL)	$t\bar{t}b\bar{b}$ (LL)
Basic	17	3.9	1.2	0.44	220	52
$ m_t^{\Delta R} - m_t < 50$ GeV	11	1.4	0.38	0.16	100	17
$m_T < 200$ GeV	8.1	0.75	0.24	0.12	67	10
$m_{b_{3j}} > 80$ GeV	3.0	0.51	0.17	0.09	60	7.0

Table 5. Expected bound on c for $\Lambda = 1$ TeV in the HL-LHC assuming no systematics. They become a factor of ~ 7 larger for a systematic uncertainty of 10%.

These bounds are competitive with (and often superior to) limits from low energy experiments and other collider searches for top production. To start with, the operators above are very poorly constrained by EWPD [22]. The qq operators are severely constrained if all flavour is assumed to be in the down sector. Indeed, in that case the interaction $\sim c_{qq}/\Lambda^2 V_{ts}^{\text{CKM}} (\bar{b}_L \gamma^\mu s_L) (\bar{s}_L \gamma_\mu b_L)$ arises. This interaction is severely constrained by current measurements of the $\bar{B}_s - B_s$ mixing parameter ΔM_s yielding $c_{qq} \lesssim 10^{-4}$ for $\Lambda \sim 1$ TeV [49].

If all flavour is in the up sector, we obtain $\sim c_{qq}/\Lambda^2 V_{ts}^{\text{CKM}} (V_{td}^{\text{CKM}})^2 (\overline{u_L} \gamma^\mu c_L) (\overline{u_L} \gamma_\mu c_L)$ and then $D-\overline{D}$ mixing excludes $c_{qq} \lesssim 1$; see e.g. ref. [50]. (Operators involving RH fields can be instead safe from flavour constraints.) Independently of the flavour assumption, these operators renormalize also dimension-six interactions such as $\mathcal{O}_{qq}^{1(3232)}$, e.g.

$$c_{qq}^{1(3232)} \sim \frac{3g_2^2}{(4\pi)^2} V_{ts}^{\text{CKM}} c_{qq}^{1(3332)} \log \frac{v}{\Lambda} \sim 10^{-4} c_{qq}^{1(3332)}, \quad (2.20)$$

with g_2 the $\text{SU}(2)_L$ gauge coupling. The bound from ΔM_s mentioned before translates however into a negligible limit on the FCNC interactions. Finally, it is also worth mentioning the reach of current measurements of the B_c^- meson lifetime. Bounds on $(\overline{\tau} \gamma^\mu \nu) (\overline{c} \gamma_\mu b) + \text{h.c.}$ four-fermion operators have been obtained e.g. in ref. [51]. They are $\mathcal{O}(1)$ for a cut-off of ~ 1 TeV. However, they are only induced after running from the four-quark operators, being the bounds on the latter therefore too weak.

Moreover, these operators contribute in general to single top production in the channel $pp \rightarrow t\overline{b}$ (and anti-particles). To the best of our knowledge, no measurement of the corresponding cross section at $\sqrt{s} = 13$ TeV has been performed. The measurement at $\sqrt{s} = 8$ TeV by the ATLAS and CMS Collaborations can be found in ref. [52], yielding $\sigma = 4.8 \pm 0.8(\text{stat.}) \pm 1.6(\text{syst.})$ pb. Being already systematically dominated, it will be hard to reduce the uncertainty below the picobarn level. On the other hand, the operators in table 5 contribute to this process via sea quarks in the proton, for which the corresponding cross sections are typically small. For example, setting only $c_{qq}^{3(3323)}/\Lambda^2 = 1 \text{ TeV}^{-2}$, we obtain $\sigma \sim 2$ pb. Therefore, searches for single-top production might improve on our bounds. Making a sharper statement about their reach is however out of the scope of this work.

3 Beyond the second generation fermions

So far we have assumed $\ell^\pm = \mu^\pm$, $j = c$. Let us now relax these assumptions. The main implication of having $j = u$ with respect to $j = c$ is the smaller misstag rate for b -tagging. It translates into an efficiency for selecting events in this new case of about $\sim 0.99/0.84 \sim 1.18$ larger. (This number agrees perfectly with the results reported in ref. [31].) In turn, the bounds on c/Λ^2 get around 1.09 times stronger. Likewise, two-quark-two-lepton operators might have $\ell^\pm = e^\pm$. The main difference with respect to the muon case is the smaller efficiency for reconstructing electrons at the detector level. Being conservative, we can estimate the reduction in efficiency by a factor of $\sim (0.77/0.94)^2 \sim 0.82^2 \sim 0.67$ [40]. In turn, the bounds on c/Λ^2 get a factor of ~ 0.82 weaker.

Two-quark-two-lepton interactions might also be LFV. In such case, the smaller number of events with SFOS leptons near the Z pole becomes far more important than the aforementioned reduced electron efficiency. This effect is exacerbated for contact-interactions involving tau leptons, due to the smaller decay rate of the latter into light leptons. For LFV operators, not only the distribution of $m_{\ell^+\ell^-}$ is different with respect to the $t \rightarrow Zj$ case. Also the distributions of $m_{\ell^+\ell^-j}$, $m_{\ell^\pm b\nu}$ and $m_{\ell^\pm \nu}$ differ from the latter and among themselves; see figure 3. The overall effect is that $\mu^\pm e^\mp$, $\mu^\pm \tau^\mp$ and $e^\pm \tau^\mp$ have much smaller

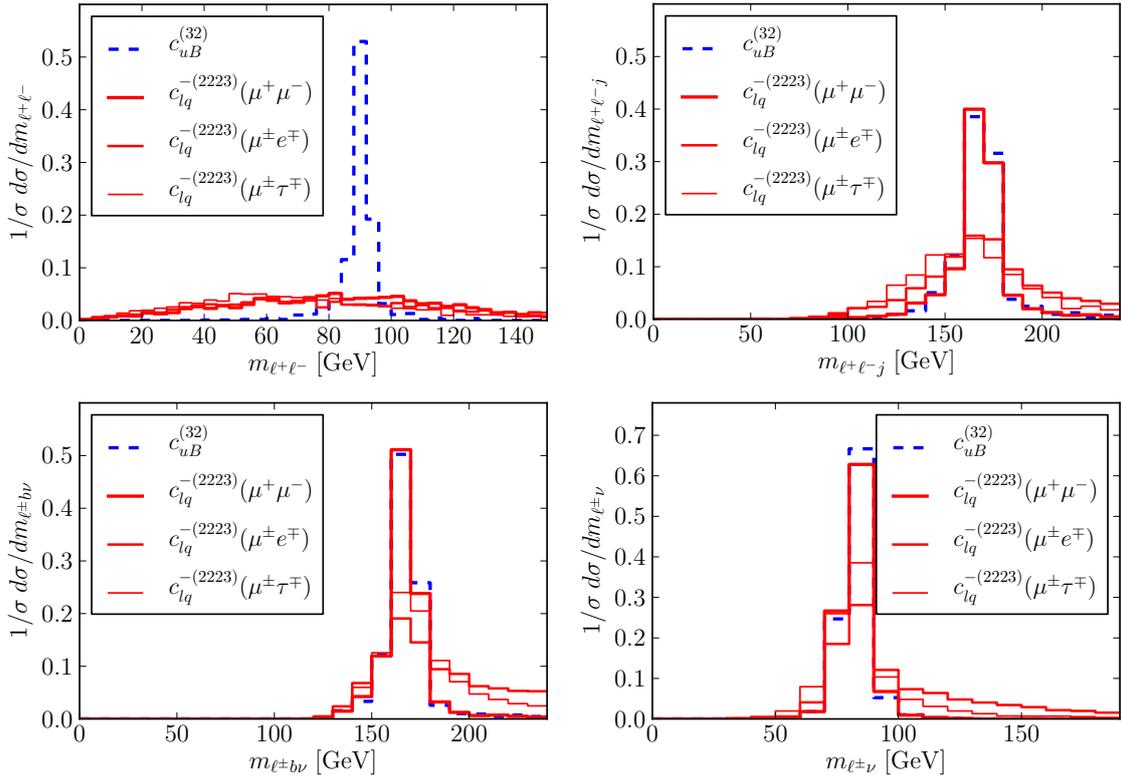

Figure 3. Top left: normalized distribution of $m_{\ell^+\ell^-}$ in the three lepton final state of top pair events with one top decaying as $t \rightarrow Zj$ (dashed blue), and in the case in which the latter decays as $t \rightarrow j\ell_i^\pm\ell_j^\mp$ (solid red) for different LFV combinations. Top right: same before but for $m_{\ell^+\ell^-j}$. Bottom left: same as before but for $m_{\ell^\pm b\nu}$. Bottom right: same as before but for $m_{\ell^\pm\nu}$.

efficiencies in SRA. In CR1, however, the impact is smaller, being the corresponding efficiencies a factor of ~ 0.90 , 0.19 and 0.16 smaller, respectively. Likewise, the efficiencies in the new region are reduced by factors of ~ 0.43 , 0.13 and 0.11 , respectively. However, the corresponding top width becomes twice larger, because the top can decay into μ^+e^- and μ^-e^+ (and analogously for taus) instead of just $\mu^+\mu^-$. Note that this assumes that both LFV couplings are present.

In summary, the coefficients of the master equation in table 1 can be trivially extrapolated to other final states using the following factors for lepton preserving processes

$$\begin{aligned} \alpha(t \rightarrow \ell_i^+\ell_j^-u) &= 1.18 \times \alpha(t \rightarrow \ell_i^+\ell_j^-c), \\ \alpha(t \rightarrow e^+e^-j) &= 0.67 \times \alpha(t \rightarrow \mu^+\mu^-j). \end{aligned} \quad (3.1)$$

For LFV processes in the CR1 signal region

$$\begin{aligned} \alpha^{\text{CR1}}(t \rightarrow \mu^\pm e^\mp j) &= 1.80 \times \alpha^{\text{CR1}}(t \rightarrow \mu^+\mu^-j), \\ \alpha^{\text{CR1}}(t \rightarrow \mu^\pm\tau^\mp j) &= 0.38 \times \alpha^{\text{CR1}}(t \rightarrow \mu^+\mu^-j), \\ \alpha^{\text{CR1}}(t \rightarrow e^\pm\tau^\mp j) &= 0.32 \times \alpha^{\text{CR1}}(t \rightarrow \mu^+\mu^-j), \end{aligned} \quad (3.2)$$

and for LFV processes in the NEW signal region

$$\begin{aligned}
 \alpha^{\text{NEW}}(t \rightarrow \mu^\pm e^\mp j) &= 0.86 \times \alpha^{\text{NEW}}(t \rightarrow \mu^+ \mu^- j), \\
 \alpha^{\text{NEW}}(t \rightarrow \mu^\pm \tau^\mp j) &= 0.26 \times \alpha^{\text{NEW}}(t \rightarrow \mu^+ \mu^- j), \\
 \alpha^{\text{NEW}}(t \rightarrow e^\pm \tau^\mp j) &= 0.22 \times \alpha^{\text{NEW}}(t \rightarrow \mu^+ \mu^- j).
 \end{aligned}
 \tag{3.3}$$

The current (future) bounds on the four-fermion operators with all flavours considered in this article in light of the new efficiencies are given in tables 6 and 7. They have been obtained using CR1 with the current luminosity (the new region at the HL-LHC). When obtaining these numbers we have considered that the two LFV couplings are equal (for instance $c_{eu}^{1232} = c_{eu}^{2132}$ and the same for all other operators).

Obviously, LFV interactions are also constrained by low-energy experiments. However, the latter are not necessarily better than the LHC. We note, for example, that c_{lq}^{1223}/Λ^2 can be bounded to $\sim 1.1 \text{ TeV}^{-2}$ in the $\mu^\pm e^\mp$ channel. *A priori*, such interaction contributes also to the process $\mu \rightarrow e\gamma$ upon closing the quark loop. At low energies, this process is mediated by the $U(1)_Q$ invariant operator $\sim \bar{\mu}_L \sigma_{\mu\nu} e_R F^{\mu\nu} + \text{h.c.}$ The latter arises from the dimension-six gauge invariant operators $\bar{L} \sigma_{\mu\nu} H e_R B^{\mu\nu} + \text{h.c.}$ and $\bar{L} \sigma_{\mu\nu} \sigma^i H e_R W_i^{\mu\nu} + \text{h.c.}$ Its size can be fairly estimated from the RGE mixing of \mathcal{O}_{lq} with the latter two. Interestingly, it vanishes at one loop. If it arises at two loops, we obtain

$$\frac{\Gamma(\mu \rightarrow e\gamma)}{\Gamma_\mu} \sim \frac{y_\mu^2 (V_{cb}^{\text{CKM}})^2 m_\mu^3 v^2 / \Lambda^4}{(4\pi)^8 m_\mu^5 / m_W^4} \sim \frac{g_2^4 (V_{cb}^{\text{CKM}})^2 v^4}{(4\pi)^8 \Lambda^4} \sim 2 \times 10^{-15}, \tag{3.4}$$

for $\Lambda \sim 1 \text{ TeV}^{-2}$. (We have approximated the muon width Γ_μ by the SM value $\sim m_\mu^5/m_W^4$; y_μ stands for the muon Yukawa.) This value is two orders of magnitude smaller than the current best bound, namely $\mathcal{B}(\mu \rightarrow e\gamma) < 4.2 \times 10^{-13}$ at the 90 % CL [53]. Moreover, the computation above is equally valid for $\tau \rightarrow \mu(e)\gamma$, for which the HL-LHC can still provide bounds much stronger than current limits from low-energy experiments, $\mathcal{B}(\tau \rightarrow \mu(e)\gamma) < 4.4(3.3) \times 10^{-8}$ at the 90 % CL [53]. RR operators are further suppressed, because the W boson does not couple to RH currents. Similar results apply to the other two-quark-two-lepton operators, with the exception of \mathcal{O}_{lequ} , which do renormalize the operators contributing to $\mu(\tau) \rightarrow e(\mu)\gamma$ at one loop, being therefore tightly constrained.

4 Matching UV models

In renormalizable weakly-coupled UV completions of the SMEFT, only new scalars and vectors can generate the operators in eqs. (2.1)–(2.8) upon integrating out at tree level. The only scalars are: $\omega_1 \sim (3, 1)_{-\frac{1}{3}}$, $\zeta \sim (3, 3)_{-\frac{1}{3}}$, $\Pi_7 \sim (3, 2)_{\frac{7}{6}}$, $\varphi \sim (1, 2)_{\frac{1}{2}}$, $\Omega_1 \sim (6, 1)_{\frac{1}{3}}$, $\Upsilon \sim (6, 3)_{\frac{1}{3}}$ and $\Phi \sim (8, 2)_{\frac{1}{2}}$. The numbers in parentheses and the subscript indicate their representations under $SU(3)_c$ and $SU(2)_L$ and the hypercharge, respectively. The relevant couplings of these particles read:

$$L_{\omega_1} = - \left\{ (y_{\omega_1}^{ql})_{rij} \omega_{1r}^\dagger \bar{q}_{Li}^c i \sigma_2 l_{Lj} + (y_{\omega_1}^{eu})_{rij} \omega_{1r}^\dagger \bar{e}_{Ri}^c u_{Rj} \right. \\ \left. + (y_{\omega_1}^{qq})_{rij} \omega_{1r}^\dagger \epsilon_{ABC} \bar{q}_{Li}^B i \sigma_2 q_{Lj}^{cC} + (y_{\omega_1}^{du})_{rij} \omega_{1r}^\dagger \epsilon_{ABC} \bar{d}_{Ri}^B u_{Rj}^{cC} + \text{h.c.} \right\} + \dots, \quad (4.1)$$

$$L_\zeta = - \left\{ (y_\zeta^{ql})_{rij} \zeta_r^{a\dagger} \bar{q}_{Li}^c i \sigma_2 \sigma^a l_{Lj} + (y_\zeta^{qq})_{rij} \zeta_r^{a\dagger} \epsilon_{ABC} \bar{q}_{Li}^B \sigma^a i \sigma_2 q_{Lj}^{cC} + \text{h.c.} \right\} + \dots, \quad (4.2)$$

$$L_{\Pi_7} = - \left\{ (y_{\Pi_7}^{lu})_{rij} \Pi_{7r}^\dagger i \sigma_2 \bar{l}_{Li}^T u_{Rj} + (y_{\Pi_7}^{eq})_{rij} \Pi_{7r}^\dagger \bar{e}_{Ri} q_{Lj} + \text{h.c.} \right\}, \quad (4.3)$$

$$L_\varphi = - \left\{ (y_\varphi^e)_{rij} \varphi_r^\dagger \bar{e}_{Ri} l_{Lj} + (y_\varphi^u)_{rij} \varphi_r^\dagger i \sigma_2 \bar{q}_{Li}^T u_{Rj} + (y_\varphi^d)_{rij} \varphi_r^\dagger \bar{d}_{Ri} q_{Lj} + \text{h.c.} \right\} + \dots, \quad (4.4)$$

$$L_{\Omega_1} = - \left\{ (y_{\Omega_1}^{ud})_{rij} \Omega_{1r}^{AB\dagger} \bar{u}_{Ri}^{c(A)} d_{Rj}^{(B)} + (y_{\Omega_1}^{qq})_{rij} \Omega_{1r}^{AB\dagger} \bar{q}_{Li}^{c(A)} i \sigma_2 q_{Lj}^{(B)} + \text{h.c.} \right\}, \quad (4.5)$$

$$L_\Upsilon = - \left\{ (y_\Upsilon)_{rij} \Upsilon_r^{aAB\dagger} \bar{q}_{Li}^{c(A)} i \sigma_2 \sigma^a q_{Lj}^{(B)} + \text{h.c.} \right\}, \quad (4.6)$$

$$L_\Phi = - \left\{ (y_\Phi^{qu})_{rij} \Phi_r^{A\dagger} i \sigma_2 \bar{q}_{Li}^T T^A u_{Rj} + (y_\Phi^{dq})_{rij} \Phi_r^{A\dagger} \bar{d}_{Ri} T^A q_{Lj} + \text{h.c.} \right\}. \quad (4.7)$$

The ellipsis indicate that other couplings are in general present, but they do not contribute to the operators under study. (Π_7 , therefore, does not induce any other operator.) Moreover, only in the case of φ , the couplings explicitly shown in eqs. (4.1) generate also interactions not considered in this article; see refs. [10, 54] for details.

On the vector side, the only possible additions are: $\mathcal{B} \sim (1, 1)_0$, $\mathcal{B}_1 \sim (1, 1)_1$, $\mathcal{W} \sim (1, 3)_0$, $\mathcal{G} \sim (8, 1)_0$, $\mathcal{G}_1 \sim (8, 1)_1$, $\mathcal{H} \sim (8, 3)_0$, $\mathcal{Q}_1 \sim (3, 2)_{\frac{1}{6}}$, $\mathcal{Q}_5 \sim (3, 2)_{-\frac{5}{6}}$, $\mathcal{Y}_1 \sim (\bar{6}, 2)_{\frac{1}{6}}$ and $\mathcal{Y}_5 \sim (\bar{6}, 2)_{-\frac{5}{6}}$. Their relevant couplings read:

$$L_{\mathcal{B}} = -\mathcal{B}^\mu \left\{ (g_{\mathcal{B}}^l)_{ij} \bar{l}_{Li} \gamma_\mu l_{Lj} + (g_{\mathcal{B}}^q)_{ij} \bar{q}_{Li} \gamma_\mu q_{Lj} + (g_{\mathcal{B}}^e)_{ij} \bar{e}_{Ri} \gamma_\mu e_{Rj} + (g_{\mathcal{B}}^u)_{ij} \bar{u}_{Ri} \gamma_\mu u_{Rj} \right. \\ \left. + (g_{\mathcal{B}}^d)_{ij} \bar{d}_{Ri} \gamma_\mu d_{Rj} \right\} + \dots, \quad (4.8)$$

$$L_{\mathcal{B}_1} = \left\{ \mathcal{B}_1^{\mu\dagger} (g_{\mathcal{B}_1}^{du})_{ij} \bar{d}_{Ri} \gamma_\mu u_{Rj} + \text{h.c.} \right\} + \dots, \quad (4.9)$$

$$L_{\mathcal{W}} = -\mathcal{W}^{\mu a} \left\{ \frac{1}{2}(g_{\mathcal{W}}^l)_{ij} \bar{l}_{Li} \sigma^a \gamma_{\mu} l_{Lj} + \frac{1}{2}(g_{\mathcal{W}}^q)_{ij} \bar{q}_{Li} \sigma^a \gamma_{\mu} q_{Lj} \right\} + \dots, \quad (4.10)$$

$$L_{\mathcal{G}} = \mathcal{G}^{\mu A} \left\{ (g_{\mathcal{G}}^q)_{ij} \bar{q}_{Li} T^A \gamma_{\mu} q_{Lj} + (g_{\mathcal{G}}^u)_{ij} \bar{u}_{Ri} T^A \gamma_{\mu} u_{Rj} + (g_{\mathcal{G}}^d)_{ij} \bar{d}_{Ri} T^A \gamma_{\mu} d_{Rj} \right\} + \dots, \quad (4.11)$$

$$L_{\mathcal{G}_1} = - \left\{ \mathcal{G}_1^{\mu A \dagger} (g_{\mathcal{G}_1})_{ij} \bar{d}_{Ri} T^A \gamma_{\mu} u_{Rj} + \text{h.c.} \right\}, \quad (4.12)$$

$$L_{\mathcal{H}} = -\frac{1}{2} \left\{ \mathcal{H}^{\mu a A} (g_{\mathcal{H}})_{ij} \bar{q}_{Li} \sigma^a T^A \gamma_{\mu} q_{Lj} \right\}, \quad (4.13)$$

$$L_{\mathcal{Q}_1} = - \left\{ \mathcal{Q}_1^{\mu \dagger} (g_{\mathcal{Q}_1}^{ul})_{ij} \bar{u}_{Ri}^c \gamma_{\mu} l_{Lj} + \mathcal{Q}_1^{A \mu \dagger} \epsilon_{ABC} (g_{\mathcal{Q}_1}^{dq})_{ij} \bar{d}_{Ri}^B \gamma_{\mu} i \sigma_2 q_{Lj}^C + \text{h.c.} \right\}, \quad (4.14)$$

$$L_{\mathcal{Q}_5} = - \left\{ \mathcal{Q}_5^{\mu \dagger} (g_{\mathcal{Q}_5}^{dl})_{ij} \bar{d}_{Ri}^c \gamma_{\mu} l_{Lj} + \mathcal{Q}_5^{\mu \dagger} (g_{\mathcal{Q}_5}^{eq})_{ij} \bar{e}_{Ri}^c \gamma_{\mu} q_{Lj} \right. \\ \left. + \mathcal{Q}_5^{A \mu \dagger} \epsilon_{ABC} (g_{\mathcal{Q}_5}^{uq})_{ij} \bar{u}_{Ri}^B \gamma_{\mu} q_{Lj}^C + \text{h.c.} \right\}, \quad (4.15)$$

$$\mathcal{Y}_1 = - \left\{ \frac{1}{2} (g_{\mathcal{Y}_1})_{ij} \mathcal{Y}_1^{AB \mu \dagger} \bar{d}_{Ri}^{(A)} \gamma_{\mu} i \sigma_2 q_{Lj}^{c(B)} + \text{h.c.} \right\}, \quad (4.16)$$

$$\mathcal{Y}_5 = - \left\{ \frac{1}{2} (g_{\mathcal{Y}_5})_{ij} \mathcal{Y}_5^{AB \mu \dagger} \bar{u}_{Ri}^{(A)} \gamma_{\mu} i \sigma_2 q_{Lj}^{c(B)} + \text{h.c.} \right\}. \quad (4.17)$$

Although all possible couplings of \mathcal{G}_1 , \mathcal{H} , \mathcal{Q}_1 and \mathcal{Q}_5 contribute to the operators of interest (that is why there are no ellipsis), they also induce other operators; see ref. [10] for further details.

The contributions of each field to the contact-interactions studied in this article after integration out can be found in tables 8, 9 and 10. Let us also remark that, in the presence of several fields in the Lagrangian, the coefficient of every dimension-six operator is the sum of the contributions of each field.

In the following, we will consider various UV completions, and compare the reach of the limits obtained in this paper with respect to the one of other searches. To start with, let us focus on new scalars. A particularly interesting example is Π_7 , because it does not generate operators others than the ones studied in this article. However, this scenario is already quite bounded by measurements of $\mathcal{B}(B_s \rightarrow s\mu\mu)$. A more interesting example is ω_1 with couplings

$$L = -\omega_1^\dagger \left[i g_{FC} \bar{\mu}_R^c c_R + g_{FV} \bar{\mu}_R^c t_R \right] + \text{h.c.} \quad (4.18)$$

At tree level, we obtain $c_{eu}^{2223} = -i g_{FV} g_{FC} / (2M^2)$, which can be probed in anomalous top decays. On top of it, one also gets $c_{eu}^{2222} = g_{FC}^2 / (2M^2)$ and $c_{eu}^{2323} = -g_{FV}^2 / (2M^2)$. The first one modifies the tail of the invariant-mass di-muon spectrum. (Resonant searches do not apply because the lepto-quark mediates in t-channel.) A naive rescaling of the bounds in ref. [18] with the larger energy, luminosity and smaller PDFs for charms with respect to valence quarks gives an estimated bound at the HL-LHC of $c_{eu}^{2222} \sim 1 \text{ TeV}^{-2}$. The second operator, instead, can be bounded from EWPD. Being the coefficient negative, however, implies that the corresponding bound is very weak [22]. The comparison between the reach of the different searches in this example is depicted in the left panel of figure 4 for $M = 2 \text{ TeV}$. For smaller masses the pair-production cross section is large enough to better test them in direct production [55, 56].

Table 10. Field-by-field contribution to four-fermion operators.

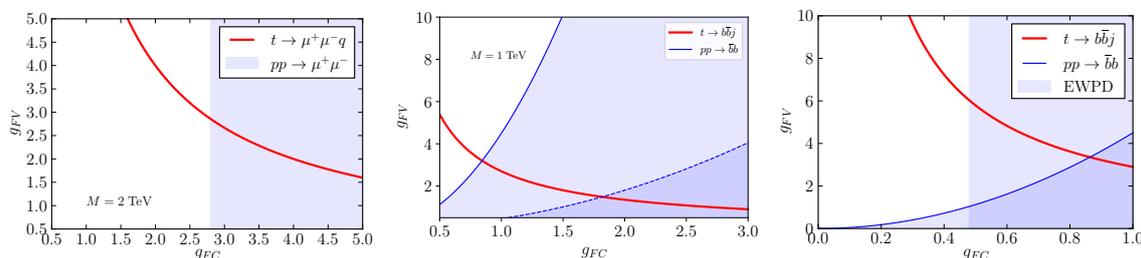

Figure 4. Parameter space region that can be bounded by rare top decays in the HL-LHC (red) versus the one that could be excluded using other searches (blue) neglecting systematic uncertainties. In the left panel we consider a scalar leptoquark extension of the SM, in the center and the right panels we consider two versions of a Z' model; see text for details.

Let us now consider the case of the Z' , complete singlet of the SM gauge group, with mass $M = 1$ TeV and couplings

$$L = Z'_\mu \left[g_{FC} \bar{b}_R \gamma^\mu b_R + \{ g_{FV} \bar{t}_R \gamma^\mu c_R + \text{h.c.} \} \right] + \dots \quad (4.19)$$

After integrating it out, we obtain $c_{ud}^{1(2333)} = g_{FC} g_{FV}$, which is constrained to be $\lesssim 2.7$ according to table 5. On the other hand, the Z' can be directly produced in pp collisions initiated by b quarks. The theoretical cross section for this process at the LHC14 is around ~ 2 pb for $g_{NC} = 1$. The branching ratio into two b -quarks is approximately given by $\mathcal{B}(Z' \rightarrow b\bar{b}) \sim g_{FC}^2 / (g_{FC}^2 + 2g_{FV}^2)$. Resonant searches at the LHC13 impose a bound on $\sigma(pp \rightarrow Z') \times \mathcal{B}(Z' \rightarrow b\bar{b})$ of around 0.5 pb [57]. A simple rescaling with the energy and luminosity enhancement shows that cross sections ten times smaller could be probed in the HL-LHC. The corresponding bounds on the g_{FC} - g_{FV} plane are depicted in the central panel of figure 4. (To the best of our knowledge, the current uncertainties in measurements of the single top production cross section make the corresponding bounds not significant.)

The shaded blue region to the right of the thin dashed line assumes $\mathcal{B}(Z' \rightarrow \text{invisible}) = 90\%$. This case arises for example in models with fermionic dark matter. Ref. [58] provides prospects for probing such invisible decays in monojet searches at the HL-LHC. Given their

results, which assume that the Z' couples predominantly to light quarks, it is unlikely that the invisible channel can trigger any sensible bound in our case. Moreover, the corresponding bound from $b\bar{b}$ searches becomes much weaker; see the dashed blue line in the same plot. It is therefore apparent that top FCNCs can provide complementary bounds in the strongly couple regime.

We repeat the previous exercise for a Z' with couplings

$$L = Z'_\mu \left[g_{FC} \bar{q}_L^3 \gamma^\mu q_L^3 + \{g_{FV} \bar{t}_R \gamma^\mu c_R + \text{h.c.}\} \right] + \dots \quad (4.20)$$

Upon integration, we get $c_{qu}^{1(3332)} = g_{FC} g_{FV}$, as well as $c_{qq}^{1(3333)} = g_{FC}^2/2$. This latter operator does not induce FCNCs, but it is constrained by EWPD. Indeed, it renormalizes the operators $\mathcal{O}_{\phi q}^{(1)}$ and $\mathcal{O}_{\phi q}^{(3)}$,

$$\frac{d(c_{\phi q}^{(1)} + c_{\phi q}^{(3)})}{d \log \mu} \sim \frac{2N_c}{(4\pi)^2} y_t^2 c_{qq}^{1(3333)}, \quad (4.21)$$

which in turn modify the $Z\bar{b}_L b_L$ coupling. Ref. [22] reports a bound of $c_{qq}^{1(3333)}/\Lambda^2 \in [-0.58, 0.23]$. Again, we have also constrains from $b\bar{b}$ resonances, as well as from $t\bar{t}$ resonances; the latter being of similar reach. They are all shown in figure 4 right.

5 Conclusions

Using the latest experimental search for $t \rightarrow Zj$, we have obtained the best collider limits on four-fermion operators leading to non-resonant $t \rightarrow \ell^+ \ell^- j$, including lepton-flavour-conserving as well as lepton-flavour-violating interactions. We have also shown that, for several operators, our bounds improve over indirect limits from low energy experiments. We have also developed modified versions of current analyses with better reach to the aforementioned dimension-six operators. We have shown that scales of about ~ 2 (3.5) TeV can be probed at the HL-LHC for couplings of order ~ 1 ($\sim \sqrt{4\pi}$). They are around a factor of 30% more stringent than the projected bounds using current searches. In light of these results, we urge the experimental collaborations to extend current analyses with signal regions outside the Z peak.

On another front, we have explored the HL-LHC reach to contact-interactions giving $t \rightarrow b\bar{b}j$. We have developed a specific analysis tailored to the kinematic of this process. We have shown that the bounds on such operators using rare-top decays can shed light on the strongly couple regime of the UV. Finally, we have also singled out all possible weakly-couple and renormalizable extensions of the SM that can generate the operators above at tree level. We have selected several of them and shown that large regions of their parameter spaces can be better tested using rare top decays than other observables.

Note added. During the last stage of this work, ref. [59] appeared on the arXiv. The latter provides bounds on an incomplete set of charged LFV four-fermion operators in top decays using a BDT analysis based on $\mathcal{L} = 79.8 \text{ fb}^{-1}$. Focusing on the $e\mu$ channel, this reference reports an expected bound of $\mathcal{B}(t \rightarrow e\mu q) < 4.8_{-1.4}^{+2.1} \times 10^{-6}$. Rescaling to

this luminosity, our expected bounds translate to a bound of $\mathcal{B}(t \rightarrow e\mu q) \lesssim 2 \times 10^{-5}$. However, we consider also non-LFV decays, as well as a full basis of the SMEFT. We strongly encourage the experimental collaborations to adopt the master equation (2.10) in this respect.
