**ABSTRACT:** We demonstrate that the gauged BPS baby Skyrme model with a double vacuum potential allows for phase transitions from a non-solitonic to a solitonic phase, where the latter corresponds to a ferromagnetic liquid. Such a transition can be generated by increasing the external pressure  $P$  or by turning on an external magnetic field  $H$ . As a consequence, the topological phase where gauged BPS baby skyrmions exist, is a higher density phase. For smaller densities, obtained for smaller values of  $P$  and  $H$ , a phase without solitons is reached. We find the critical line in the  $P, H$  parameter space. Furthermore, in the soliton phase, we find the equation of state for the baby skyrmion matter  $V = V(P, H)$  at zero temperature, where  $V$  is the “volume”, i.e., area of the solitons.

**KEYWORDS:** Field Theories in Lower Dimensions, Solitons Monopoles and Instantons, Topological States of Matter

**1 Introduction**

The baby Skyrme model [1, 2] (see also [3–18]) is a lower dimensional version of the 3 + 1 dimensional Skyrme model [19–21], that is, an effective theory of the low energy, non-perturbative sector of Quantum Chromodynamics. It plays an important role as a toy model for the higher dimensional theory. In fact, many aspects of the original Skyrme proposal were understood qualitatively by the investigation of its 2 + 1 dimensional counterpart. Recently, it has been understood that the correct Skyrme model should be a near BPS theory [22–25] where the BPS part gives the main contribution to some static observables [26, 27] (see also [28–31]). A concrete near BPS Skyrme action has been proposed in [22, 23]. Indeed, already its BPS part leads to very accurate results not only for the binding energies of the atomic nuclei [22, 23] and some thermodynamical properties [32] of nuclear matter, but also for the physics of neutron stars [33] (maximal masses and radii, equation of state). There are, therefore, strong arguments for the assumption that this near BPS Skyrme model, providing an unified description of nuclear matter from baryons with the baryon charge  $B = 1$  and nuclei  $B \sim 10^2$  to neutron stars  $B \sim 10^{57}$ , is a good candidate for the correct low-energy effective model of QCD.

Qualitatively, the BPS Skyrme model consists of two terms: the topological (baryon) current squared and a potential. Obviously, there is a baby version of the BPS Skyrme model [34–38] (for some near BPS extension see [39]). Both theories have many features in common: 1) the existence of the linear energy — topological charge bound which is saturated by infinitely many solutions with arbitrary topological charge; 2) the invariance of the static energy integral under the SDiff symmetries and the resulting close relation to a perfect fluid as the corresponding state of matter; 3) the possibility to identify certain global observables of the field theory with the corresponding thermodynamic variables, which turn out to obey the standard thermodynamical relations.

Recently, the BPS baby Skyrme model has been used to investigate magnetic properties of skyrmions after minimal coupling to the Maxwell electrodynamics [40, 41]. Interestingly, the gauged BPS baby Skyrme model also allows for a  $N = 2$  supersymmetric extension, see, e.g., [39, 42–44]. Undoubtedly, the interaction with an abelian gauge field is very important for properties of baryons and atomic nuclei. It is a well-known result by Witten that, although the precise form of the low energy effective Skyrme-type theory is still unknown, its coupling to the electromagnetic  $U(1)$  field is completely fixed [45–47]. Hence, in principle, one can study electromagnetic properties of skyrmions once a particular model is chosen. In practice, however, this is a rather complicated task even within the framework of the BPS Skyrme model, and not many results are available (for the standard Skyrme model see [48, 49] and [50]). Again, the BPS baby Skyrme model serves here as a perfect laboratory (for gauged solitons in a related Skyrme-Faddeev-Niemi model see [51]).

The aim of the present paper is to further investigate the gauged BPS baby Skyrme model [40, 41]. Specifically, we would like to analyze the issue of the (non)existence of planar skyrmions in the model with double vacuum potentials. It is one of the most surprising findings in our former work that, in contrast to one vacuum potentials, the gauged BPS baby Skyrme model does not support solitons for potentials with two vacua. This unexpected observation (there is no such difference for the non-gauged case, see for example recent works for the Skyrme model [52, 53]) was made for BPS configurations, i.e., with zero external pressure and no external magnetic field. Here we will show that solitons can exist if these two *external* parameters are larger than some minimal *critical* values. Hence a phase transition between a solitonic phase and a non-solitonic phase is observed.

## 2 The gauged BPS baby Skyrme model

The gauged BPS baby Skyrme model is given by the following Lagrangian density

$$\mathcal{L} = -\frac{\lambda^2}{4} \left( D_\mu \vec{\phi} \times D_\nu \vec{\phi} \right)^2 - \mu^2 U(\vec{n} \cdot \vec{\phi}) + \frac{1}{4g^2} F_{\mu\nu}^2 \quad (2.1)$$

where the covariant derivative reads [54, 55]

$$D_\mu \vec{\phi} \equiv \partial_\mu \vec{\phi} + A_\mu \vec{n} \times \vec{\phi}. \quad (2.2)$$

As usual, without loss of generality, we assume that the constant vector  $\vec{n} = (0, 0, 1)$  and the potential  $U$  is a function of the third component of the unit vector field  $\vec{\phi} = (\phi_1, \phi_2, \phi_3)$ . The gauge field is the Maxwell field with the electromagnetic coupling constant  $g$ . Here we list the main properties of this model (for details we refer to [41]).

### *i) BPS bound*

The static energy (or regularized energy for a non-zero constant external magnetic field  $H$ )

$$E_{\text{reg}} = \frac{E_0}{2} \int d^2x \left[ \lambda^2 \left( D_1 \vec{\phi} \times D_2 \vec{\phi} \right)^2 + 2\mu^2 U + \frac{1}{g^2} (B - H)^2 \right] \quad (2.3)$$

is bounded from below by the topological charge  $k$

$$E_{\text{reg}} \geq 4\pi|k|E_0\lambda^2\langle W' \rangle_{S^2}. \quad (2.4)$$

Here  $B$  is the magnetic field (pseudoscalar in  $2 + 1$  dimensions),  $W$  is the so-called superpotential (depending on the target space variable  $\phi_3$ ) defined as a solution of the first order differential equation

$$\lambda^2 W'^2 + g^2 \lambda^4 W^2 - 2\lambda^2 W H = 2\mu^2 U, \quad (2.5)$$

and  $\langle W' \rangle_{S^2}$  is its average value over the target space manifold. The prime denotes differentiation with respect to  $\phi_3$ .

*ii) BPS equations*

The bound is saturated by solutions of the BPS equations

$$Q = W' \quad (2.6)$$

$$B = -g^2 \lambda^2 W + H \quad (2.7)$$

where

$$Q = q + \epsilon_{ij} A_i \partial_j (\vec{n} \cdot \vec{\phi}), \quad q = \vec{\phi} \cdot \partial_1 \vec{\phi} \times \partial_2 \vec{\phi} \quad (2.8)$$

and  $q$  is the topological charge density. Further, the static energy functional is invariant under spatial SDiff transformations, therefore there exist infinitely many solutions with arbitrary shapes for each topological charge  $n$ .

*iii) No solitons for two-vacuum potentials*

The existence of such solutions is a rather subtle issue as the superpotential  $W$  has to obey certain boundary conditions, and the resulting solution of eq. (2.5) must exist over the whole interval  $\phi_3 \in [-1, 1]$ . This requirement is quite restrictive and, for example, *cannot be satisfied* in the case of two vacuum potentials and  $H = 0$ . The fact that BPS baby skyrmions for two-vacuum potentials can be destabilized by the electromagnetic interaction was quite surprising since no similar effect was known in the non-gauged case.

*iv) Magnetization*

The thermodynamic magnetization  $M$ , defined as minus the change of the thermodynamic energy of a sample (in our case, the skyrmion) under a variation of the external magnetic field

$$M = -\frac{\partial E_{\text{reg}}}{\partial H} \quad (2.9)$$

exactly coincides with the usual definition of magnetization as the difference between full and external magnetic flux in the sample

$$M = \frac{1}{g^2} \int (B - H) d^2x. \quad (2.10)$$

Furthermore, the matter described by the gauged BPS Skyrme model behaves as a rather *nonlinear ferromagnetic medium* where the solitons remain magnetized even

when the external magnetic field vanishes, i.e., they possess a permanent magnetization. The external magnetic field  $H$  acts in two ways: it changes the size of the baby skyrmions (it squeezes the soliton if it has the same sign like the permanent magnetization  $M$  of the skyrmion, while it enlarges the skyrmion if  $H$  and  $M$  have opposite signs) and interferes with the magnetic field inside the solitons: for an external magnetic field  $H$  which is sufficiently weak and oppositely oriented to  $M$ , the phenomenon of magnetic flux inversion occurs. That is, the total magnetic field  $B$  flips sign in a shell region near the boundary of the skyrmion, as it has to take the value  $B = H$  at the boundary. On the other hand, it preserves its original sign resulting from the permanent magnetization in the interior (core region) of the skyrmion.

*v) Non-BPS (external pressure) solutions*

Solutions with a non-zero *field theoretical pressure* ( $P = -T_{ii}$ , where  $T_{\mu\nu}$  is the energy-momentum tensor with the constant external magnetic part subtracted) are described by the same first order BPS equations but with a modified superpotential equation

$$\lambda^2 W'^2 + g^2 \lambda^4 W^2 - 2\lambda^2 WH = 2\mu^2 U + 2P. \tag{2.11}$$

The pressure introduced in this way obeys the usual thermodynamical relation

$$P = -\frac{\partial E_{\text{reg}}}{\partial V} \tag{2.12}$$

where  $V$  is the geometrical (compacton) “volume” (area) and therefore agrees with the thermodynamical pressure.

*vi) BPS-induced thermodynamics*

The model has the surprising property that certain global (bulk) observables resulting from exact field theory solutions may be interpreted as thermodynamic variables obeying the standard thermodynamic relations, although no statistical physics methods and no thermodynamical limit intervened in their calculation. The soliton energy, the geometric soliton volume (area) and the pressure (an integration constant of the static field equations), e.g., are related by the thermodynamic relation (2.12). Here,  $E_{\text{reg}}$  and  $V$  are extensive quantities (they are exactly proportional to the “particle number”, i.e., the topological charge  $n$ ), whereas  $P$  is intensive (does not depend on  $n$ ). Further, the magnetization (2.10) obeys the thermodynamical relation (2.9). The proofs for these thermodynamical relations involve the BPS equations, therefore we call these thermodynamical relations “BPS-induced”, although this issue certainly deserves further investigation. Further, the static energy functional is SDiff invariant both without and with a static magnetic field, therefore for each topological charge  $n$  there exist infinitely many soliton solutions with arbitrary shapes, leading exactly to the same bulk observables and to the same thermodynamic relations. These thermodynamic relations, therefore, depend on the BPS equations but not on the specific solutions and, as such, are properties of the model itself.

### 3 The new baby potential

In order to understand how the external magnetic field and/or pressure may influence the existence of planar solitons in the case of two vacuum potentials we have to analyze the necessary condition for the existence of BPS gauged baby skyrmions, that is, the existence of a global solution to the superpotential equation

$$\lambda^2 W'^2 + g^2 \lambda^4 W^2 - 2\lambda^2 W H = 2\mu^2 U + 2P. \quad (3.1)$$

Concretely, we shall consider the so-called new baby potential

$$U = \frac{1}{4}(1 - \phi_3^2). \quad (3.2)$$

The next step (if the superpotential exists) is to solve the corresponding equations of motion. Here we assume the standard axially symmetric static ansatz

$$\vec{\phi}(r, \phi) = \begin{pmatrix} \sin f(r) \cos n\phi \\ \sin f(r) \sin n\phi \\ \cos f(r) \end{pmatrix}, \quad A_0 = A_r = 0, \quad A_\phi = na(r) \quad (3.3)$$

which leads to an identically vanishing electric field and to the magnetic field  $B = \frac{na'(r)}{r}$ . Moreover, we introduce a new base space variable  $y = r^2/2$  and target space variable  $h$  via

$$\phi_3 = \cos f \equiv 1 - 2h \Rightarrow h = \frac{1}{2}(1 - \cos f), \quad h_y = \frac{1}{2} \sin f f_y. \quad (3.4)$$

Then the first order field equations (BPS equations) read

$$2nh_y(1 + a) = -\frac{1}{2}W_h \quad (3.5)$$

$$na_y = -g^2 \lambda^2 W + H \quad (3.6)$$

where the following boundary condition

$$h(0) = 1, \quad h(y_P) = 0, \quad (3.7)$$

$$a(0) = 0, \quad a_y(y_P) = \frac{H}{n} \quad (3.8)$$

guarantee the nontrivial topology ( $n$  is just the topological charge) and finiteness of the (regularized) energy

$$E_{\text{reg}} = 2\pi \int dy \left( 2\lambda^2 n^2 (1 + a)^2 h_y^2 + \mu^2 h(1 - h) + \frac{1}{2g^2} n^2 a_y^2 \right). \quad (3.9)$$

Here,  $y_P$  is the size of the compacton for a non-zero value of the pressure  $P$ . Since we deal with compact solutions one can define the geometrical volume (area)

$$V = 2\pi y_P \quad (3.10)$$

which, as we remarked before, together with the pressure fulfills the usual thermodynamical relation. The superpotential equation in terms of the new variable  $h$  reads

$$\frac{\lambda^2}{4}W_h^2 + g^2\lambda^4W^2 - 2\lambda^2WH = 2\mu^2U + 2P. \quad (3.11)$$

Further, we always assume that the Skyrme field approaches the vacuum at  $h = 0$  at the compacton radius  $r_P = \sqrt{2y_P}$ . This, together with the boundary conditions and BPS equations for  $h$  and  $a$ , implies that the superpotential  $W(h)$  must obey the boundary conditions

$$W(0) = 0, \quad W_h(0) = \pm \frac{2}{\lambda}\sqrt{2P}. \quad (3.12)$$

For nonzero pressure this implies that the first derivative  $h_y$  jumps at the compacton boundary. This is as it should be, because if we impose a nonzero external pressure at the soliton surface (compacton boundary), then the energy density must jump there.

In numerical computations we assumed  $\lambda = 1$  and  $\mu^2 = 0.1$ , while the electromagnetic coupling constant was kept as a free parameter. Furthermore, a particular value of the topological charge  $n$  can be eliminated from the field equation by the coordinate redefinition  $\tilde{y} = y/n$  rendering the numerics  $n$  independent (with a linear dependence of the energy and volume on  $n$  — as expected for a BPS model). Therefore we present all plots for  $n = 1$ .

### 3.1 $H = 0, P = 0$

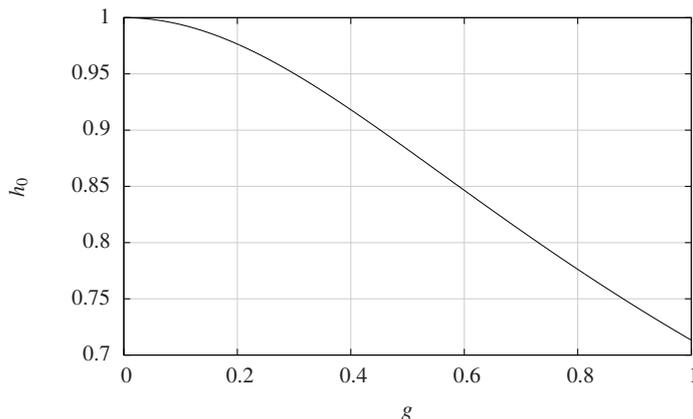

Let us begin with the case where  $H = 0, P = 0$ . It is straightforward to see that we arrive at some difficulties. Indeed, the superpotential equation

$$\frac{\lambda^2}{4}W_h^2 + g^2\lambda^4W^2 = 2\mu^2h(1-h) \quad (3.13)$$

enforces boundary conditions at both ends of the unit interval. In addition to  $W(0) = 0$ , we must impose  $W(1) = 0$ . However, for a first order equation it is in general impossible that both conditions can be simultaneously obeyed. Indeed, if we numerical solve equation (3.13) then a singularity occurs for  $h = h_0$ . (Strictly speaking  $W_h(h_0) = 0$  while  $W_{hh}(h_0) = \infty$ .) It approaches the boundary of the interval as the electromagnetic coupling constant goes to 0, see figure 1. Then, for  $g = 0$  we arrive at the non-gauge case for which BPS skyrmions do exist and read

$$h(y) = \begin{cases} \sin^2 \frac{\pi}{2} \left(1 - \frac{y}{y_0}\right) & y \leq y_0 \\ 0 & y \geq y_0 \end{cases}, \quad \text{where } y_0 = \frac{n\pi\lambda}{4\mu}. \quad (3.14)$$

Obviously, the nonexistence of the superpotential shows that gauged solitons do not show up if the pressure as well as the external magnetic field vanish (for any value of  $g > 0$ ). It is also clearly visible that in the more general situation, with nonzero value for the external parameters  $P$  and  $H$ , the superpotential might exist on the full unit interval for some external parameter values.

**Figure 1.** The position of the singularity in the superpotential  $W$  for  $H = 0$  and  $P = 0$ , as a function of the coupling constant  $g$ .

### 3.2 $H = 0, P > 0$

Now let us turn on the pressure, still assuming  $H = 0$ , at the boundary of compactons. For the limiting case, when  $g = 0$ , the exact solutions are known [41]

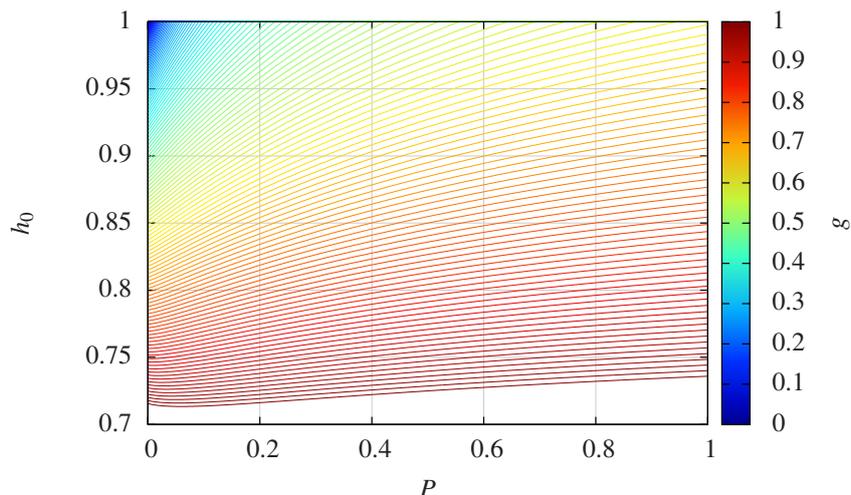

$$\frac{1 - 2h}{2\sqrt{\frac{P}{\mu^2} + h(1 - h)}} = \tan \frac{\mu}{n\sqrt{2}\lambda}(y - y_0), \quad \text{where} \quad \tan \frac{\mu y_0}{n\sqrt{2}\lambda} = \frac{\mu}{\sqrt{P}} \quad (3.15)$$

leading to the following equation of state

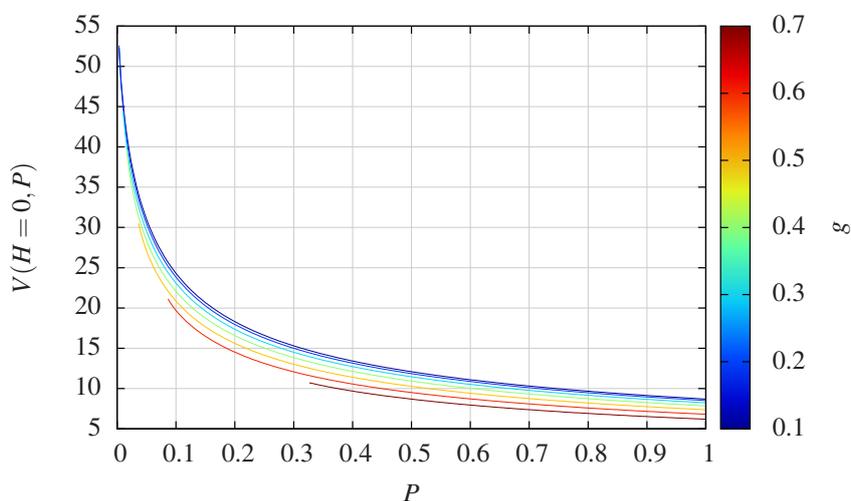

$$V = \frac{4\sqrt{2}\pi\lambda n}{\mu} \arctan \frac{\mu}{\sqrt{P}}. \quad (3.16)$$

Hence, for  $P \rightarrow 0$  we find the volume  $V_{\max} = \frac{2\sqrt{2}\pi^2\lambda n}{\mu}$ . This is the maximal volume for topological charge  $n = 1$ . For higher charge solutions, the volume can be further increased by using the fact that, in our model, soliton solutions for arbitrary charge are compactons, which deviate from their vacuum value only in a finite area. Among the infinitely many solutions for higher charge  $n$  there exist, therefore, always “gaseous” solutions at zero pressure, which consist of a collection of non-overlapping smaller charge constituents with empty space (vacuum) in between, such that the amount of empty space may be increased without cost in energy. This phase resembles a gas of BPS skyrmions. On the other hand, for  $V < V_{\max}$  we have a sort of liquid phase. Therefore, one can conclude that we observe a liquid-gas phase transition at  $P = 0$  (at  $g = 0$ , i.e., in the absence of electromagnetic coupling). In fact, such a behavior is a generic feature of BPS Skyrme models in any dimension [32].

If the electromagnetic coupling constant is not zero, then solutions exist only for  $P \geq P_{\min}$ . At the critical minimal pressure  $P_{\min}$  the system reaches its maximal volume  $V_{\max}(P)$ . For  $P < P_{\min}$  the superpotential develops a singularity for  $h_0 < 1$ , see figure 2, and solutions cease to exist. Hence, at  $P_{\min}$  another phase transition occurs between a topologically trivial phase (no solitons) and a skyrmionic matter phase. One can

**Figure 2.** The position of the singularity for the superpotential for  $H = 0$ . For  $h_0 \geq 1$  solutions do exist.

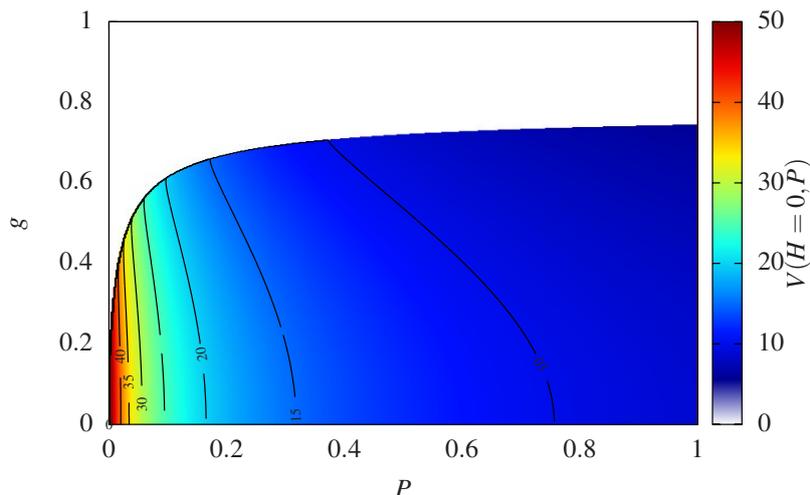

**Figure 3.** Volume vs. pressure, for different values of the coupling constant  $g$ .

also say that the gauged BPS skyrmions are pressure induced objects. In figure 3, we plot the equation of state  $V = V(P)$  for the skyrmionic phase for several values of the electromagnetic coupling constant. The ends of the curves correspond to  $P_{\min}$  and  $V_{\min}$ . A detailed plot is presented in figure 4, where the line of minimal pressure is visible as a function of  $g$ .

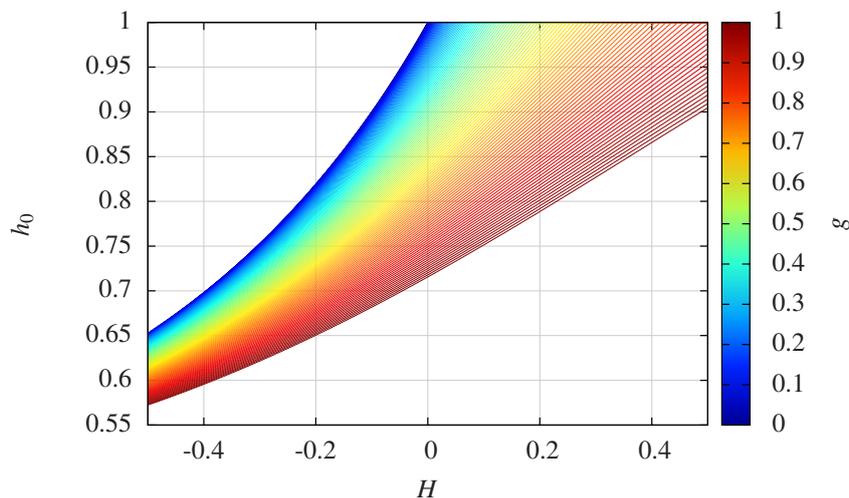

### 3.3 $H \neq 0, P = 0$

Another possibility to create solitons, i.e., to extend the existence of the superpotential on the whole unit interval, is to consider a non-vanishing external magnetic field  $H > 0$  together with  $P = 0$ ,

$$\frac{\lambda^2}{4} W_h^2 + g^2 \lambda^2 W^2 = 2\mu^2 U + 2\lambda^2 W H. \quad (3.17)$$

**Figure 4.** The volume as a function of pressure  $P$  and coupling constant  $g$ . The white region denotes no solutions.

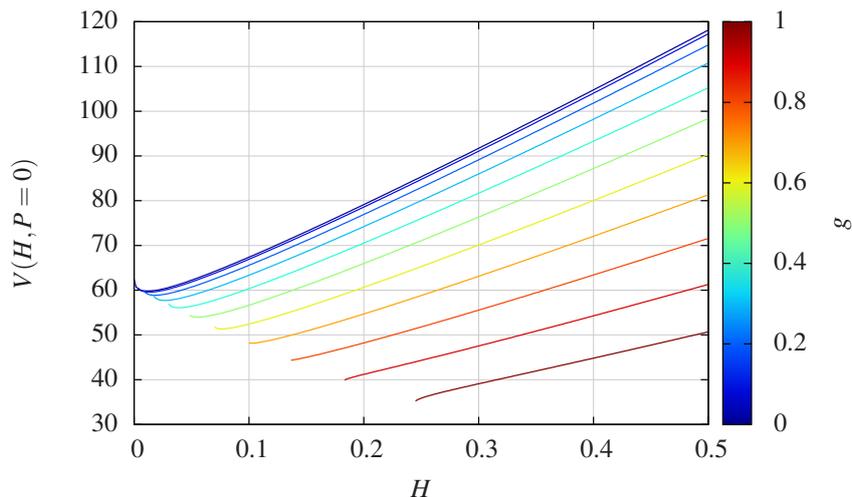

**Figure 5.** The position of the singularity for the superpotential for  $P = 0$ . For  $h_0 \geq 1$  solutions do exist.

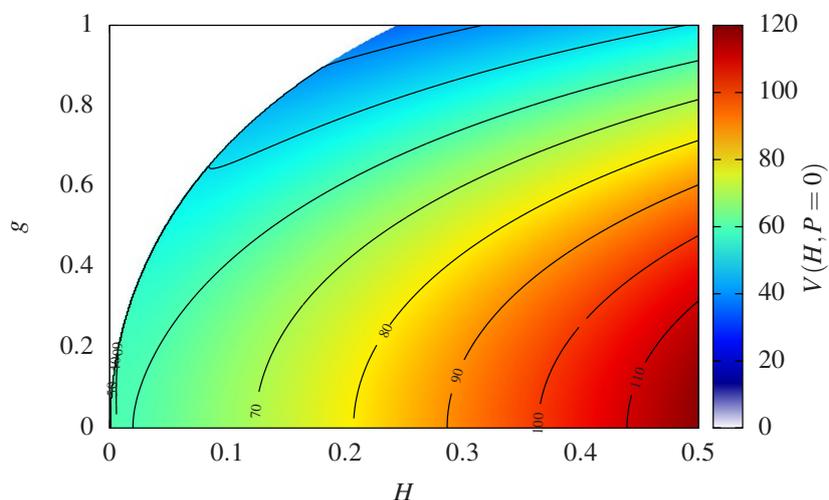

Let us start with the limiting case when  $g = 0$ . The corresponding superpotential equation is

$$\frac{\lambda^2}{4} W_h^2 = 2\mu^2 U + 2\lambda^2 W H. \quad (3.18)$$

It is not difficult to show that  $W_h$  will never take the value zero on the unit segment (except at  $h = 0$ ). Indeed, assuming the positive square root we find that  $W_h > 0$  in the vicinity of  $h = 0$ . Then, the right hand side of the equation is always greater than 0 as  $U \geq 0$  and  $W$  is a growing function. A consequence of that is the existence of solitons for any  $H$  (for  $g = 0$  and  $P = 0$ ). Again, if  $g > 0$ , the original ( $H = 0$ ) singularity moves towards the boundary of the unit segment, reaching it for a certain minimal value of the magnetic field  $H_{\min}$ , figure 5. Starting with this minimal value, the external magnetic field creates

**Figure 6.** Volume vs. pressure, for different values of the coupling constant  $g$ .

**Figure 7.** The volume as a function of the external magnetic field  $H$  and coupling constant  $g$ . The white region denotes no solutions.

a skyrmionic phase. Now, the volume increases with the magnetic field, figure 6, as the magnetization inside the solitons is opposite to the orientation of the external field. A more detailed equation of state  $V = V(H)$  for different  $g$  is presented in figure 7.

It is a surprising feature of the gauged BPS baby Skyrme model that the limiting case,  $g = 0$ , can be solved exactly although the superpotential is not known analytically. Let us write the full second order field equation for the Skyrme field assuming the non-back reaction approximation (equivalent to  $g = 0$ ), i.e.,  $a = \beta y$  where  $\beta \equiv H/n$ . Then,

$$\partial_y [h_y(1+a)^2] = \frac{\mu^2}{4n^2\lambda^2}(1-2h) \Rightarrow \partial_y [h_y(1+\beta y)^2] = \frac{\mu^2}{4n^2\lambda^2}(1-2h). \quad (3.19)$$

Now we introduce the new variable

$$z = \frac{1}{1+\beta y}. \quad (3.20)$$

Then,

$$z^2 h_{zz} = \frac{\mu^2}{4n^2 \lambda^2 \beta^2} (1 - 2h) \equiv \alpha(1 - 2h) \quad (3.21)$$

with the following general solution: for  $\alpha < \frac{1}{8}$

$$h(z) = C_1 z^{\frac{\sqrt{1-8\alpha}+1}{2}} + C_2 z^{\frac{-\sqrt{1-8\alpha}+1}{2}} + \frac{1}{2}, \quad (3.22)$$

for  $\alpha > \frac{1}{8}$

$$h(z) = C_1 \sqrt{z} \sin\left(\frac{\sqrt{8\alpha-1}}{2} \ln z\right) + C_2 \sqrt{z} \cos\left(\frac{\sqrt{8\alpha-1}}{2} \ln z\right) + \frac{1}{2}. \quad (3.23)$$

The boundary conditions

$$h(z=1) = 1, \quad h(z_0) = 0, \quad h_z(z_0) = 0 \quad (3.24)$$

lead to the following solution ( $\alpha < 1/8$ )

$$h(z) = \frac{1}{2} - \frac{\sqrt{z}}{2} \left( \frac{1}{\sqrt{z_0} \sin(\omega \ln z_0)} + \cot(\omega \ln z_0) \right) \sin(\omega \ln z) + \frac{1}{2} \sqrt{z} \cos(\omega \ln z), \quad (3.25)$$

where  $\omega \equiv \sqrt{8\alpha-1}$  and the position of the compacton boundary is given by

$$\sin(\omega \ln z_0) + \omega \cos(\omega \ln z_0) = -2\omega \sqrt{z_0}. \quad (3.26)$$

Hence, we find the equation of state relating the volume  $V = 2\pi y_0$  and the magnetic field

$$\begin{aligned} & \sin \left[ \frac{1}{2} \sqrt{\frac{\mu^2}{2H^2 \lambda^2} - 1} \ln \left( 1 + \frac{HV}{2\pi n} \right) \right] + 2 \sqrt{\frac{\mu^2}{2H^2 \lambda^2} - 1} \cos \left[ \frac{1}{2} \sqrt{\frac{\mu^2}{2H^2 \lambda^2} - 1} \ln \left( 1 + \frac{HV}{2\pi n} \right) \right] \\ &= -2 \sqrt{\frac{\frac{\mu^2}{2H^2 \lambda^2} - 1}{1 + \frac{HV}{2\pi n}}} \end{aligned} \quad (3.27)$$

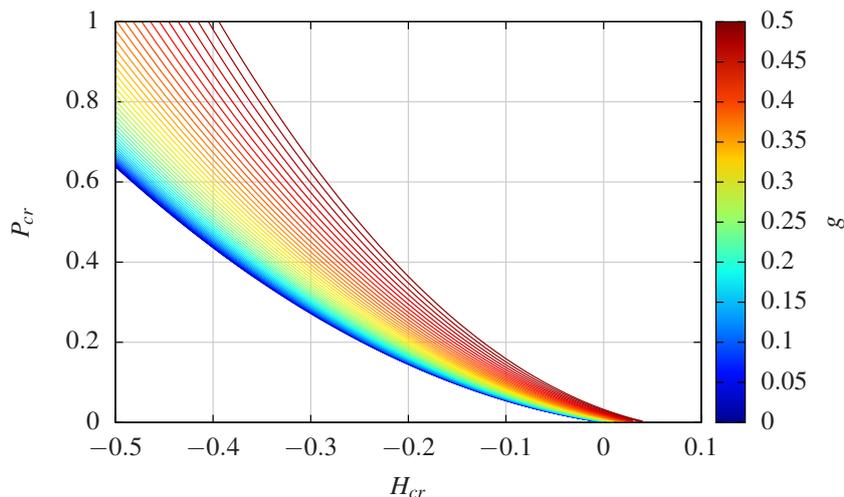

for the external magnetic field obeying

$$H < \frac{\mu}{\lambda \sqrt{2}}. \quad (3.28)$$

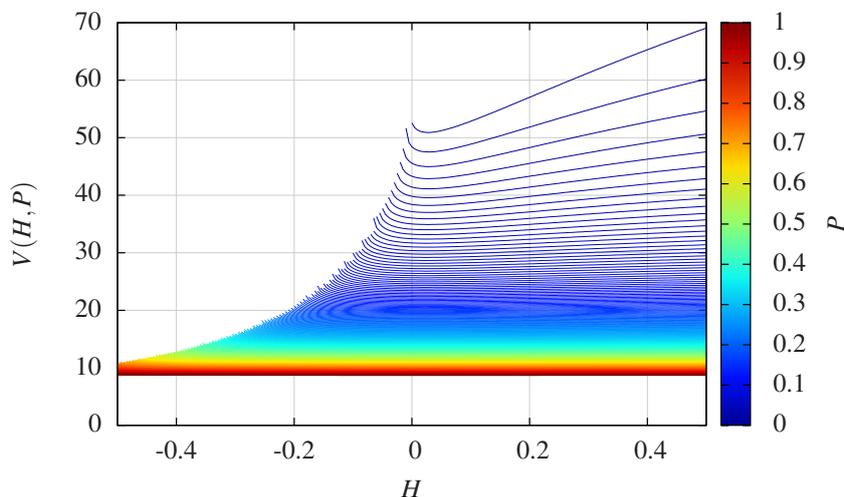

If the magnetic field is bigger than this value one has to change to the hyperbolic functions resulting in

$$\begin{aligned} & -\sinh \left[ \frac{1}{2} \sqrt{1 - \frac{\mu^2}{2H^2 \lambda^2}} \ln \left( 1 + \frac{HV}{2\pi n} \right) \right] + 2 \sqrt{1 - \frac{\mu^2}{2H^2 \lambda^2}} \cosh \left[ \frac{1}{2} \sqrt{1 - \frac{\mu^2}{2H^2 \lambda^2}} \ln \left( 1 + \frac{HV}{2\pi n} \right) \right] \\ &= -2 \sqrt{\frac{1 - \frac{\mu^2}{2H^2 \lambda^2}}{1 + \frac{HV}{2\pi n}}}. \end{aligned} \quad (3.29)$$

These results give us the approximated equation of state  $V = V(H)$  for small value of the electromagnetic coupling constant.

**Figure 8.** Critical line for different values of the coupling constant  $g$ . Above the line the topological phase exists while below the line we have the non-topological phase.

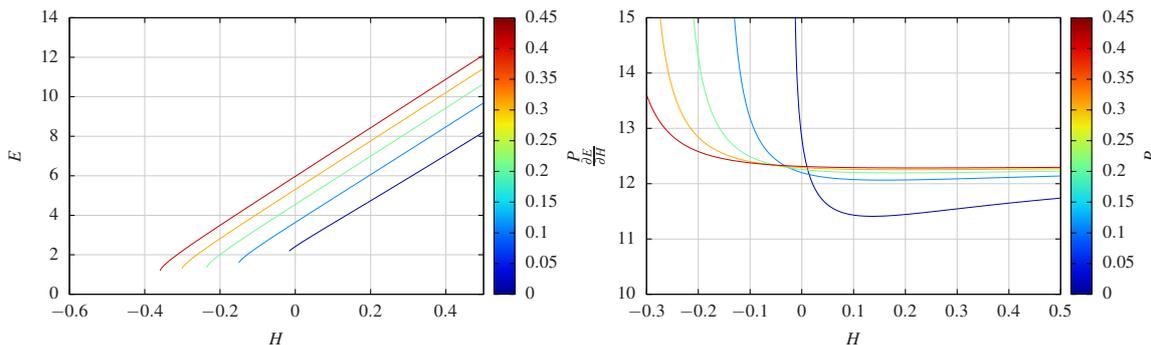

**Figure 9.** The volume as a function of  $P$  and  $H$ . Here  $g = 0.2$ .

### 3.4 $H \neq 0, P \neq 0$

In the most general situation, one imposes the external pressure as well as the external magnetic field. Again, solitons are observed for sufficiently large  $P$  and  $H$ . In fact, one can plot a critical curve in the  $P, H$  plane above which the solitonic phase exists, see figure 8. The corresponding equation of state  $V = V(H, P)$ , for  $g = 0.2$ , is presented in figure 9. The dependence of the regularized energy, as well as its derivative, on the magnetic field  $H$  for several values of  $P$  (and  $g = 0.2$ ) are presented in figure 10.

The soliton medium possesses a permanent magnetization, that is, a non-trivial magnetic field inside the solitons, even for vanishing external magnetic field. Of course, this makes sense only if such solitons do survive in the  $H = 0$  limit, which requires a sufficiently large non-vanishing external pressure. We plot the magnetization in figure 11. It is always

**Figure 10.** Regularized energy and its derivative as a function of  $H$  for different value of the pressure  $P$ . Here  $g = 0.2$ .

negative and grows to a constant value in the limit of very large pressure. In figure 12 we show the magnetic susceptibility at  $H = 0$ . There is a qualitative difference to the one-vacuum potential case: although the regularized energy is a monotonously growing function with  $H$  (positive first derivative and negative magnetization), it is a concave function (with negative second derivative respect to  $H$ ). This happens for any  $P$ . Hence, the magnetic susceptibility (at  $H = 0$ ) is always positive,

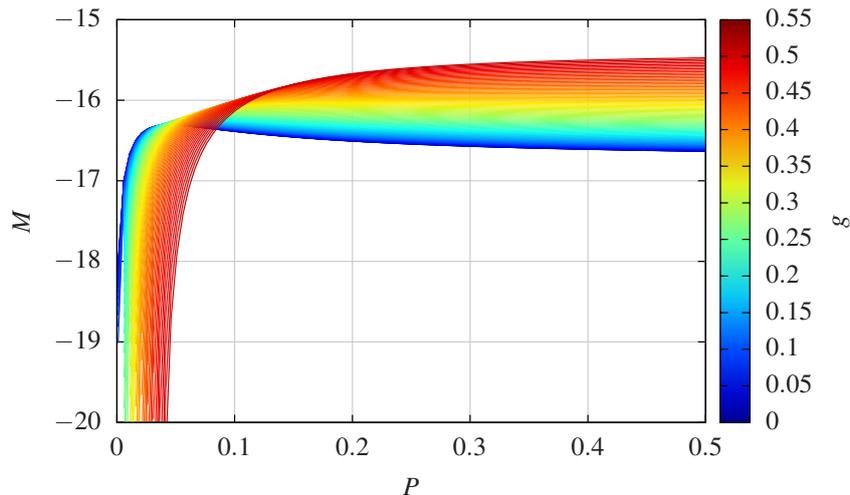

$$\chi_0(P) = - \left. \frac{\partial^2 E_{\text{reg}}}{\partial H^2} \right|_{H=0} > 0. \tag{3.30}$$

This behavior does not change the type of the magnetic medium described by the model. It is still a ferromagnetic medium as we have a permanent magnetization, and the field wants to join the external field smoothly. It simply shows that the BPS Skyrme model with the new baby potential responds in a very nonlinear way to the external magnetic field.

#### 4 Summary

In this paper, we have analyzed the gauged BPS baby Skyrme model with a two vacuum potential. It has been shown that although there are no baby skyrmions in the “unperturbed” case (no pressure and vanishing magnetic field at the compacton boundary), such solitons do appear if an external pressure and/or a constant external magnetic field are applied. Strictly speaking, baby skyrmions exist if these parameters are above their critical values  $P_{\text{min}}, H_{\text{min}}$ . The resulting critical curves (in the  $P, H$  plane) have been obtained for several values of the electromagnetic coupling constant. Such a curve divides the system into two phases, a solitonic and a non-solitonic one, and crossing the curve corresponds to a phase transition from the topological to the non-topological phase.

Otherwise, the thermodynamical and magnetic properties of the model in the solitonic phase are qualitatively very similar to the previously analyzed one vacuum case. The baby skyrmions form a non-linear ferromagnetic, i.e. permanently magnetized, type of matter (except for the  $P < P_{\text{crit}}(g)$  case, where the non-solitonic phase is reached as  $H \rightarrow 0$ ). Let us note that a topology changing phase transition is a known phenomenon in Skyrme

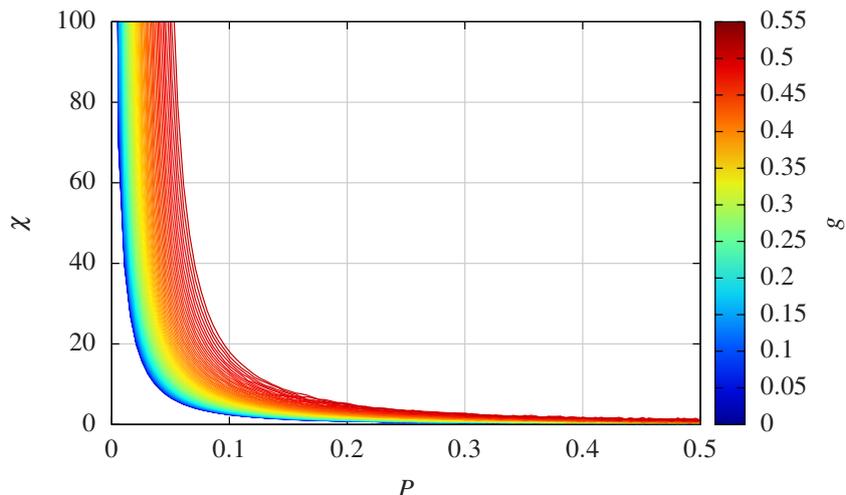

**Figure 11.** Magnetization at  $H = 0$  as a function of the pressure, for different  $g$ .

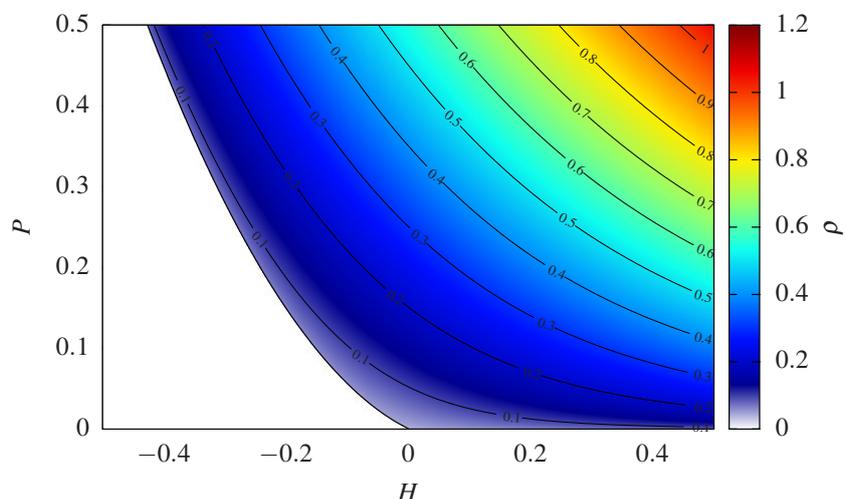

models. For example, a transition between phases with skyrmions and half-skyrmions was proposed in the context of dense nuclear matter [56–58] (neutron stars). Specifically, the crystal phase formed by skyrmions transforms, as the density of the matter *increases*, into a different crystal phase where the building blocks are half-skyrmions, instead. In our case, however, the approach to the phase transition is quite different. Namely, one can start in the topological phase and then, assuming a fixed value of the external magnetic field  $H$ , reduce the pressure until one reaches the non-topological phase. As the pressure decreases, the size of the skyrmions grows (pressure always squeezes the solitons in the BPS Skyrme models), and the average energy density ( $\rho_{\text{average}} \equiv E_{\text{reg}}/V$ ) decreases, figure 13. Hence, the non-skyrmion phase occurs for lower densities. In other words, in the model with the new baby potential, the BPS baby skyrmions appear only if the medium has a sufficiently high density.

There are several directions in which the present investigation may be continued. For example, one may be interested in how the magnetic and thermodynamic properties of the gauged BPS baby skyrmions are modified by the (iso)spin. The isospinning BPS baby skyrmions are known [34], and it would be interesting to look for such solutions also in the gauged version of the model (Isospinning baby skyrmions and 3 + 1 dim skyrmions have been recently considered in [11, 12] and [59, 60]).

Unfortunately, there are a lot of problems and modifications which must be solved before we could extrapolate these results to the 3 + 1 dimensional (near) BPS Skyrme model. First of all, the planar case is a bit special with respect to the magnetic field. Indeed, here  $B$  is a pseudo-scalar instead of a pseudo-vector. Moreover, in contrast to to the planar case, the gauging of the BPS Skyrme model will break the SDiff invariance in the static sector. Furthermore, the proper, QCD-induced, coupling to the abelian gauge field requires also the Wess-Zumino-Witten term, which leads to a non-zero electric field inside the skyrmions. Finally, the inclusion of non-BPS terms, i.e., the sigma model term and the Skyrme term, may modify the magnetic properties of the system. In any case,

**Figure 12.** Susceptibility at  $H = 0$  as a function of the pressure, for different  $g$ .

**Figure 13.** Average density for  $g = 0.1$ . The white region denotes the non-solitonic phase.

the first step should be a derivation of the energy minimizers in the non-gauge near BPS Skyrme model, which is a difficult numerical issue [61] (for some recent numerical result in the Skyrme model with the sextic term see [52, 53, 62]).

Moreover, there exists the possibility that the gauged BPS baby Skyrme model is the proper effective description of some real physical  $2 + 1$  dimensional systems. Such systems should form an almost BPS liquid with an at least approximate realisation of the SDiff symmetry at low temperature. Moreover, perturbative excitations around the vacuum, governed by the relative strength of the potential part of the BPS baby model, on the one hand, and the non-BPS addition, i.e., the usual sigma model part, on the other hand, should possess rather large masses. In fact, there is a vast literature on planar solitons of the baby skyrme type topology in a magnetized medium (see, e.g., [63] and the references quoted there). The relevant topological order parameter is a local magnetization which can

interact with an external magnetic field. It would be very desirable to rewrite the gauged baby BPS Skyrme model in terms of magnetization and compare with such systems. This issue is under current investigation.
