## Materials and Methods

## Materials

Chloroform (Sigma-Aldrich, $\geq 99 \%$ ), methanol (Alfa, 99.8\%), acetic acid (Alfa, 99.9\%), DIO (Sigma-Aldrich, 98\%), 1-CN (TCI, 97\%) and 1,4-diiodobenzene (TCI, 98\%) were purchased from commercial sources and used without further purification. PM6, PM7, D18, ITIC, IT4F, IDIC, Y6, BTP-eC9, PFN-Br, and PDINN were purchased from Solarmer Material Inc. D18-Cl and PNDIT-F3N were purchased from eFlexPV Limited. PTQ10 was purchased from 1-Material Inc. L8-BO, IDTT-C10-TIC, and PBT1-C-2Cl were designed and synthesized by Yanming Sun's group.

## Measurements and instruments

UV-vis absorption spectra were recorded on a Shimadzu spectrometer model UV-1800 with films on the quartz plates at room temperature. Ultraviolet photoelectron spectrometer (UPS) measurement was performed by AXIS ULTRA DLD instrument of Kratos company. The UV light source used is non-monochromatic He I, and the energy of He I light source is 21.22 eV . The basic vacuum of the analysis chamber is $3.0 \times 10^{-8}$ Torr, and the bias voltage applied during the test is -9 V . Inverse photoemission spectroscopy (IPES) measurement was performed using a customized ULVAC-PHI LEIPS instrument with Bremsstrahlung isochromatic mode. TEM measurements were carried out on a JEOL JEM-1400 (Japan) transmission electron microscope. AFM measurements were performed using a Dimension Icon AFM instrument (Bruker) in the tapping mode. SEM measurements were carried out on a GeminiSEM 500 (ZEISS Co., Germany) scanning electron microscope. The GIWAXS characterization of the thin films was performed at the Advanced Light Source (Lawrence Berkeley National Laboratory) on beamline 7.3.3. The incidence angle was $0.16^{\circ}$, and the beam energy was 10 keV . Samples were prepared under device conditions on the Si/PEDOT:PSS substrates. RSoXS was performed at beamline 11.0.1.2 (ALS, LBNL) with different bean energies. Samples were prepared under device conditions on the Si/PEDOT:PSS substrates, then placed in water and transferred to a silicon nitride window. The scattering signals were collected in a vacuum using a Princeton Instrument-motion tracking enhancement technique (PI-MTE) charge-coupled device (CCD) camera. Polarized resonant X-ray scattering (PSoXS) was performed to elucidate the relative orientation of the components in the active layers.

## Device characterization

The current-voltage ( $J-V$ ) curves were measured with Keithley 2400 Source under the illumination of AM $1.5 \mathrm{G}^{2}$ irradiation ( $100 \mathrm{~mW} \mathrm{~cm}{ }^{-2}$ ) using a 150 W solar simulator (DM40S3, SAN-EI ELECTRIC, Japan) in a glove box at room temperature. The light intensity was determined by a $2 \times 2 \mathrm{~cm}^{2}$ standardized mono silicon cell (Oriel PN 91150V, Newport, USA.) calibrated by the National Renewable Energy Laboratory (NREL). The external quantum efficiency (EQE) measurement was conducted on a TRACQ-BASIC System using a lock-in amplifier with a monochromator and 500 W xenon lamp. A calibrated silicon detector (PRL-12, Newport, USA) with a known photoresponse was utilized as a reference. The $J-V$ curves were measured along the reverse scan direction from 1.0 to -0.1 V , yielding identical results. The scan speed and dwell times were fixed at $0.02 \mathrm{~V} /$ step and 20 ms , respectively. During the test, an aperture with an area of 3.2 or $10.4 \mathrm{~mm}^{2}$ is used to calibrate the device area.

## Photo-induced force microscope (PiFM)

For tapping PiFM measurements, an IR-neaSCOPE from neaspec was used to map IR absorption via detecting the mechanical response of an AFM cantilever upon sample stimulation by pulsed IR light. In the instrument, a pulsed tunable QCL laser is focused onto a PtIr coated AFM probe via a parabolic mirror, while the microscope is operated in the intermittent contact mode. The readout of the optically induced changes in the sample is performed by providing bimodal excitation of the cantilever and monitoring the response at the second cantilever Eigen-mode, while the first Eigen-mode is used for AFM topography and feedback. Such an active bimodal technique enables reliable tracking of the cantilever resonance, which in turn suppresses mechanically induced artifacts in the PiFM image contrasts. The pulse width of the QCL laser is in the ns range in tapping PiFM operation. The linewidth of the laser is typically about $1 \mathrm{~cm}^{-1}$. The accessible spectral range depends on the selection of central wavelengths when equipping the laser. Up to 4 ranges can be selected and within those ranges, the laser is freely tunable. In this measurement mode, a resolution of $\sim 1$ $\mathrm{cm}^{-1}$ can be achieved within the tuning range of the laser.

## SCLC mobility measurements

The electron-only devices were fabricated with ITO/ZnO/Active layer/ZnO/Ag structures and hole-only devices were fabricated with ITO/PEDOT:PSS/active layer/Au structures. The thickness of the active layer is $\sim 120 \mathrm{~nm}$. The mobilities were extracted using a full drift
diffusion model simulation (gpvdm) ${ }^{1,2}$ with gaussian type trap states, and the parameters are listed in Supplementary Table 8. Key input parameters are the trap profiles, including the total trap density, trap depth, and the trap state gaussian width, which were estimated using capacitance-frequency measurements as presented in Supplementary Fig. 27. This leads to only two fitting parameters to extract the mobilities, which are the injection barriers (e and h). The fitted curves and the resulting mobility values are shown in Supplementary Fig. 25 and Supplementary Table 9, respectively.

## Transient photovoltage (TPV) and photocurrent (TPC) measurements

The background illumination was provided by the LED light source, and pulsed light was provided by an arbitrary wave generator (AFG322C, Tektronix). The photovoltage traces were registered by the oscilloscope (AFG322C, Tektronix). The photocurrent traces were registered with the resistance of $50 \Omega$, switching open-circuit mode to short-circuit mode. The integrated TPC signal provides a measure of the total charge generated by the LED light source. The exponential fitting was used to process the $V-t$ curves measuring from the TPV signal to obtain the lifetime of carriers. The total charge generated by LED was obtained from the integrated TPC signal. Empirically, the differential capacitance values are found to follow the exponential dependence on the open-circuit voltage given by $C=\frac{\Delta Q}{\Delta V_{0}}=C_{0} \exp \left(\gamma V_{\mathrm{oc}}\right)+D$ [ $C$ is the differential capacitance ( F ), $\Delta Q$ is the total charge generated by a pulse ( C ), $\Delta V_{0}$ is the TPV magnitude (V), $C_{0}$ is the exponential capacitance prefactor ( F ), $\gamma$ is the capacitance exponential constant $\left(\mathrm{V}^{-1}\right), D$ is the effectively fixed capacitance ( F )], so the charge-carrier density as a function of $V_{\text {oc }}$ is given by treating the device as a parallel-plate capacitor and integrating with respect to voltage, as $n=\frac{1}{A e d} \int_{-\infty}^{V_{0 c}} C_{0} \exp (\gamma V) \mathrm{d} V[n$ is the bulk chargecarrier density $\left(\mathrm{m}^{-3}\right), A$ is the area of the device $\left(\mathrm{m}^{2}\right), d$ is the thickness of the active layer $(\mathrm{m})]^{3}$ Then, the recombination rate coefficient can be determined, which is defined by $k(n)=\frac{1}{\tau(n) \cdot n}$.

## Impedance spectroscopy (IS)

The measurements were carried out by illumination with an AM 1.5 G irradiation ( 100 mW $\mathrm{cm}^{-2}$ ) using a solar simulator. Impedance spectra were measured for different light intensities at frequencies from 8 MHz to 50 Hz . To measure in $V_{\text {oc }}$ conditions, a bias voltage equal to $V_{\text {oc }}$
at each light intensity was applied. A 10 mV AC perturbation is used, and in this case, the excess holes and electrons are generated into the donor HOMO and acceptor LUMO manifolds, then diffuse along with the diode bulk, and eventually recombine. The molecular orbitals spread in energy DoS following the exponential shape, and the occupancy level of the LUMO state is determined by the competition of photo-generation and recombination, which in turn governs the achievable $V_{\mathrm{oc}}$. Recombination resistance ( $R_{\mathrm{rec}}$ ) and chemical capacitance ( $C_{\mu}^{n}$ ) were directly extracted from the low-frequency region. The chemical capacitors determined by IS reflect the capability of the photovoltaic device to accept or release additional charge carriers as the result of the shifting in the quasi-Fermi level. The $\operatorname{DoS}\left(g_{\mathrm{n}}\right)$ is obtained by $C_{\mu}^{n}=S q g_{\mathrm{n}}\left(E_{\mathrm{Fn}}\right)$, where $S$ is the device area and $q$ is the elemental charge. A typical exponential shape is seen, and the curves are fitted by $g_{\mathrm{n}}\left(E_{\mathrm{Fn}}\right)=\frac{N}{\delta} \exp \left(-\frac{E_{\mathrm{g}}-E_{\mathrm{Fn}}}{\delta}\right)$, where $N$ is the total density per unit volume, $E_{\mathrm{g}}$ is the bandgap extracted from the EQE tail, and $\delta$ is the broadening of the $\operatorname{DoS}$ that describes energetic disorder.

The curves of $C_{\mu}^{n}$ and $R_{\mathrm{rec}}$ are fitted by $C_{\mu}^{n}=C_{0} \exp \left(\frac{\alpha q V}{k T}\right)$ and $R_{\mathrm{rec}}=R_{0} \exp \left(-\frac{\beta q V}{k T}\right)$. The density of electrons $n$ is the integration of $C_{\mu}^{n}$ to voltage, so the density of electrons $n$ is proportional to $\exp \left(\frac{\alpha q V}{k T}\right)$, that is $n \propto \exp \left(\frac{\alpha q V_{\mathrm{F}}}{k T}\right)$. If one further assumes that the dominant recombination process is mono- or bimolecular, recombination current $J_{\text {rec }}$ will be proportional to $n$ or $n^{2}$, so $J_{\text {rec }} \propto \exp \left(\frac{\alpha q V}{k T}\right)$ or $J_{\text {rec }} \propto \exp \left(\frac{2 \alpha q V}{k T}\right)$. In open-circuit conditions, $J_{\text {rec }}$ is phenomenologically modeled as $J_{\text {rec }}=J_{0}\left[\exp \left(\frac{\alpha q V}{k T}\right)-1\right]$. Therefore, validation of the recombination law can be reinforced from the experimental relationships between $\alpha$ and $\beta$ parameters. As for the mono-molecular recombination process, it is derived that $\beta=\alpha$, and for the bimolecular recombination process, $\beta=2 \alpha$. If considering shallow trapped carriers in the exponential tail as the dominant non-geminate loss mechanism, the corresponding recombination current is $J_{\text {rec }} \propto n \cdot n_{\mathrm{t}}$, in which the density of trapped carriers $\left(n_{\mathrm{t}}\right)$ relates to free carriers ( $n$ ) by $n_{\mathrm{t}} \propto n^{k T / E_{\mathrm{U}}}$. Then, it is derived that $J_{\text {rec }} \propto n_{\mathrm{t}}^{E_{\mathrm{J}} / k T+1}$, and if $E_{\mathrm{U}}>k T$, then $\beta>2 \alpha$.

## Transient absorption spectroscopy (TA)

For femtosecond transient absorption spectroscopy, the fundamental output from $\mathrm{Yb}: \mathrm{KGW}$ laser ( $1030 \mathrm{~nm}, 220 \mathrm{fs}$ Gaussian fit, 100 kHz , Light Conversion Ltd) was separated into two light beams. One was introduced to NOPA (ORPHEUS-N, Light Conversion Ltd) to produce a certain wavelength for pump beam (here we use 550 and $750 \mathrm{~nm}, 30 \mathrm{fs}$ pulse duration), the other was focused onto a YAG plate to generate white light continuum as the probe beam. The pump and probe overlapped on the sample at a small angle of less than $10^{\circ}$. The transmitted probe light from the sample was collected by a linear CCD array.

## Exciton annihilation method

The exciton annihilation method is used to estimate the diffusion length of each neat films ${ }^{4,5}$. The series of fluence dependent decays are globally fit to a rate equation accounting for bimolecular (exciton annihilation) and monomolecular decay pathways, assuming that annihilation destroys both excitons: $\frac{\mathrm{d} n(t)}{\mathrm{d} t}=-k n(t)-\frac{1}{2} \gamma n^{2}(t)$ (1), which has the following solution: $n(t)=\frac{n(0) e^{-k t}}{1+\frac{\gamma}{2 k} n(0)\left(1-e^{-k t}\right)}(2)$, where $n(t)$ is the singlet exciton density as a function of time after the laser excitation, $k$ is the monomolecular decay rate and $\gamma$ is the singletsinglet bimolecular exciton annihilation rate. Here the intrinsic monomolecular decay constant, $k$, is extracted from the dilute neat film under weak laser irradiation ( $<1 \mu \mathrm{~J} \mathrm{~cm}^{-2}$ ). The exciton decays can be well fit by Eq. (2), where the only free parameter is the bimolecular rate constant. The bimolecular rate constant is then used $D=\frac{\gamma}{8 \pi R}$ to determine the 3 D exciton diffusion coefficient, where $D$ is the diffusion constant and $R$ is the effective interaction or annihilation radius of singlet excitons which is the separation at which the annihilation occurs. The Förster radius for exciton-exciton annihilation of 4.8 nm was adopted from previous research, which then gives a 3D diffusion coefficient ${ }^{4}$.

## Supplementary Figures

Supplementary Figure 1. UV-vis absorption spectra of D18, PM6, and L8-BO neat films (a) and D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO blend films (b) processed by CF.

Supplementary Figure 2. UPS (a) and IPES (b) results of PM6, D18, and L8-BO. Fermi energy was determined by linear extrapolating the high binding energy portion of the spectrum, and HOMO energy level was referred to low binding energy onset. The LUMO energy level was obtained by linear extrapolation of the initial peak of IPES.

Supplementary Figure 3. $J-V$ curves of the device based on D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO (0.8:0.2:1.2) with a device area of $14.2 \mathrm{~mm}^{2}$.

Page 7 of 7 Pages

Supplementary Figure 4．Original images of the OSC certificate results by the National Photovoltaic Industry Metrology and Testing Center（NPVM，China）．The device is measured with a mask of \(3.084 \mathrm{~mm}^{2}\) and gives a PCE of \(19.17 \%\) ．

Supplementary Figure 5. \(J-V\) (a) and EQE (b) curves of the device based on PM6:D18:L8BO under different PM6:D18 ratios. (c) The integrated \(J_{\text {sc }}\) curves under different donor conditions (device area was \(5.2 \mathrm{~mm}^{2}\) ).

Supplementary Figure 6. Storage (a) and illumination (b) stability of the device based on D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO. The storage stability was tested for 2520 hours, the device was encapsulated and stored in a glove box at \(25^{\circ} \mathrm{C}\). The illumination stability was tested for 350 hours. The device was encapsulated and then tested in the atmosphere under the illumination of AM \(1.5 \mathrm{G}, 100 \mathrm{~mW} / \mathrm{cm}^{2}\).

Supplementary Figure 7. IQE, EQE, and reflectance curves of binary and ternary devices.

Supplementary Figure 8. TEM image of D18:L8-BO blended film.

Supplementary Figure 9. AFM height (first row) and phase (second row) images of D18:L8BO, PM6:L8-BO, and PM6:D18:L8-BO (0.8:0.2:1.2) blended films. The line profile to obtain the fibril width (third row) and the statistical distribution (fourth row) for the three blended films.

Supplementary Figure 10. (a) SEM image of PM6:D18:L8-BO \(=0.8: 0.2: 1.2\) blended film (insert is Fourier transformed image). (b) Circle integration of the 2D Fourier transformed image.

Supplementary Figure 11. FTIR spectra of PM6, D18, and L8-BO.

Supplementary Figure 12. (a) PiFM image at the wavenumber of \(2215 \mathrm{~cm}^{-1}\) (at this wavenumber, L8-BO was absorbed, which was consistent with the PiFM image at \(1532 \mathrm{~cm}^{-1}\). Further confirmed the fibril network structure formed by L8-BO). (b) The PiFM images overlapped at the wavenumber of \(1532 \mathrm{~cm}^{-1}\) and \(1648 \mathrm{~cm}^{-1}\) (The black spots in the image are used for positioning). (c) PiFM image at the wavenumber of \(1850 \mathrm{~cm}^{-1}\) (at this wavenumber, both PM6, D18, and L8-BO have no signal).

Supplementary Figure 13. (a) 2D GIXD patterns of neat D18, PM6, and L8-BO films. (b) The in-plane and out-of-plane line cut profiles of the 2D GIXD data based on neat films. (c) 2D GIXD patterns of D18:L8-BO blended film. (d) The line cut profiles diagram of (021) diffraction peak. (e) The line cut profiles of the 2D GIXD data based on binary and ternary blend films in a \(56^{\circ}\) azimuthal angle plane.

Supplementary Figure 14. Peak area and CCL of (010) and (100) diffraction peaks for D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO (0.8:0.2:1.2) blended films.

Supplementary Figure 15. Peak area and CCL of L8-BO (021) and D18 (001) diffraction peaks for D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO (0.8:0.2:1.2) blended films.

Supplementary Figure 16. (a,b) The near-edge x-ray absorption fine structure spectroscopy (NEXAFS) of neat films under different energy ranges. Contrast functions for the neat (c) and blended (d) materials with vacuum ( \(\mathrm{n}=1\) ). The mass density of each material was assumed to be \(1.0 \mathrm{~g} / \mathrm{cm}^{3}\).

Supplementary Figure 17. CK-RSoXS profiles and polarized RSoXS of D18:L8-BO (a), PM6:L8-BO (b), and PM6:D18:L8-BO (c) blends under different photon energies. (d) NKRSoXS profiles of D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO blends under different photon energies.

Supplementary Figure 18. The color plot of fs transient absorption spectra of neat L8-BO film under \(750 \mathrm{~nm}(\mathrm{a}, \mathrm{b})\) excitation and the representative fs transient absorption spectra of neat L8-BO film at indicated delay times under \(750 \mathrm{~nm}(\mathrm{c}, \mathrm{d})\) excitation.

Supplementary Figure 19. The color plot of fs transient absorption spectra of PM6:D18:L8BO ( \(0.8: 0.2: 1.2\) ) film under \(750 \mathrm{~nm}(\mathrm{a}, \mathrm{b})\) excitation and the representative fs transient absorption spectra of PM6:D18:L8-BO (0.8:0.2:1.2) film at indicated delay times under 750 \(\mathrm{nm}(\mathrm{c}, \mathrm{d})\) excitation.

Supplementary Figure 20. The color plot of fs transient absorption spectra of PM6:L8-BO film under \(750 \mathrm{~nm}(\mathrm{a}, \mathrm{b})\) excitation and the representative fs transient absorption spectra of PM6:L8-BO film at indicated delay times under \(750 \mathrm{~nm}(\mathrm{c}, \mathrm{d})\) excitation.

Supplementary Figure 21. The color plot of fs transient absorption spectra of D18:L8-BO film under \(750 \mathrm{~nm}(\mathrm{a}, \mathrm{b})\) excitation and the representative fs transient absorption spectra of D18:L8-BO film at indicated delay times under \(750 \mathrm{~nm}(\mathrm{c}, \mathrm{d})\) excitation.

Supplementary Figure 22. The hole transfer process in D18:L8-BO (yellow dots), PM6:L8BO (blue dots), and PM6:D18:L8-BO (red dots) blended films (the solid line is the fitting curves).

Supplementary Figure 23. The TA kinetics of polaron state of neat L8-BO and three blend films.

Supplementary Figure 24. Characteristics of the photocurrent density versus effective voltage ( \(J_{\text {ph }} \sim V_{\text {eff }}\) ) based on D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO (0.8:0.2:1.2). \(J_{\text {ph }}=J_{\mathrm{L}}-J_{\mathrm{D}}, J_{\mathrm{L}}\) and \(J_{\mathrm{D}}\) are light and dark current density, \(V_{\text {eff }}=V_{0}-V_{\text {appl }}, V_{\text {appl }}\) is the applied voltage and \(V_{0}\) is the voltage when \(J_{\mathrm{ph}}=0 \mathrm{~mA} \mathrm{~cm}^{-2}\).

Supplementary Figure 25. Mobility measurements. SCLC measurement for electron-only (a) and hole-only (b) devices under different components. The slopes of each curve are shown in (c) and (d). In all devices, a maximum slope of \(\sim 2\) is observed, indicating a negligible role of trap states. The fitting was done using a full drift diffusion model using gpvdm, and the details of fitting are presented in the methods section in Supplementary Information.

Supplementary Figure 26. Lifetime (a) and charge-carriers density (b) under different \(V_{\text {oc }}\) conditions. (c) Charge lifetime in the devices as a function of charge density. The solid lines represent the best fit to power-law dependence.

Supplementary Figure 27. The defects density of state (a) and built-in potential (b) of binary and ternary devices measured following the Mott-Schottky method at 10 kHz in the dark.

Supplementary Figure 28. The impedance spectra of binary and ternary devices measured under different light intensities.

Supplementary Figure 29. The chemical capacitance ( \(C_{\mu}^{n}\), a-c) and recombination resistance ( \(R_{\text {rec }}, \mathrm{d}-\mathrm{f}\) ) extracted from the low-frequency region of impedance spectra.

Supplementary Figure 30. 3D sphere for exciton diffusion simulations.

Supplementary Figure 31. Optical constants for D18:L8-BO, PM6:L8-BO, and PM6:D18:L8-BO blends, obtained from ellipsometry measurements.

Supplementary Figure 32. Device simulation results. (a) Internal and external quantum efficiency (solid lines are simulation results, dashed lines are experimental results). (b) Simulated current-voltage characteristics (solid lines) as compared to experimental values (dashed lines). (c) Simulated FFs as a function of direct recombination coefficient ( \(B_{\text {dir }}\) ), and the values for each device are highlighted. (d) Figure-of-merit \((\alpha)\) on the competition between recombination and transport. Values for each device have been highlighted in the plots. The figure is adapted from reference \({ }^{6}\).

Supplementary Figure 33. The exciton decay kinetics of L8-BO neat film at indicated excitation fluences.

Supplementary Figure 34. The color plot of fs transient absorption spectra of different NFA films (Y6, BTP-eC9, L8-BO, ITIC, IT4F, and IDIC) under 750 nm excitation.

Supplementary Figure 35. The representative fs transient absorption spectra of different NFA films (Y6, BTP-eC9, L8-BO, ITIC, IT4F, and IDIC) at indicated delay times under 750 nm excitation.

Supplementary Figure 36. The color plot of fs transient absorption spectra of different donor films (PM6, PM7, PTQ10, D18, D18-Cl, and PBT1-C-2Cl) under 750 nm excitation.

Supplementary Figure 37. The representative fs transient absorption spectra of different donor films (PM6, PM7, PTQ10, D18, D18-Cl, and PBT1-C-2Cl) at indicated delay times under 750 nm excitation.

Supplementary Figure 38. The color plot of fs transient absorption spectra of different double blended donor films (PM6:D18=4:1, PM7:D18=4:1, PTQ10:D18=4:1, PM6:D18\(\mathrm{Cl}=4: 1\), and \(\mathrm{PM} 6: \mathrm{PBT} 1-\mathrm{C}-2 \mathrm{Cl}=4: 1\) ) under 750 nm excitation.

Supplementary Figure 39. The representative fs transient absorption spectra of different double blended donor films (PM6:D18=4:1, PM7:D18=4:1, PTQ10:D18=4:1, PM6:D18\(\mathrm{Cl}=4: 1\), and \(\mathrm{PM} 6: \mathrm{PBT} 1-\mathrm{C}-2 \mathrm{Cl}=4: 1\) ) at indicated delay times under 750 nm excitation.

IDTT-C10-TIC

Supplementary Figure 40. Chemical structure of the donor and acceptor materials used in device fabrication.

Supplementary Figure 41. \(J-V\) curves of binary and ternary OSCs with PM6 as the donor and different NFAs under the illumination of AM \(1.5 \mathrm{G}, 100 \mathrm{~mW} / \mathrm{cm}^{2}\) (the dotted line is for the binary device while the solid line is for the ternary device).

Supplementary Figure 42. \(J-V\) curves of binary and ternary OSCs with D18 as the secondary donor, L8-BO (a) and Y6 (b) as acceptor, and different primary donors (PM6, PM7, and PTQ10) under the illumination of AM \(1.5 \mathrm{G}, 100 \mathrm{~mW} / \mathrm{cm}^{2}\).

Supplementary Figure 43. \(J-V\) curves of binary and ternary OSCs with PM6 as the primary donor, L8-BO (a) and Y6 (b) as acceptor, and different secondary donors (D18, D18-Cl, and PBT1-C-2Cl) under the illumination of AM \(1.5 \mathrm{G}, 100 \mathrm{~mW} / \mathrm{cm}^{2}\).

Supplementary Figure 44. (a) \(J-V\), (b) TPV, and (c) TA curves, and (e) carrier diffusion length and the lifetime of hole transfer process under different blend conditions.

Supplementary Figure 45. AFM phase images of PM6:D18:L8-BO \(=0.5: 0.5: 1.2\) and PM6:D18:L8-BO \(=0.2: 0.8: 1.2\) blended films. The line profile to obtain the fibril diameter of both blended films, and the corresponding fibril diameters of PM6:D18:L8-BO \(=0.5: 0.5: 1.2\) and PM6:D18:L8-BO \(=0.2: 0.8: 1.2\) are 19.6 and 18.1 nm , respectively. (b) RSoXS profiles under 285.2 eV based on PM6:D18:L8-BO with different donor ratios.

Supplementary Figure 46. Correlation matrix. Correlation of device, photophysics, and morphology characters (based on PM6:D18:L8-BO with different donor ratios). The photovoltaic, photophysical, and morphological characteristic parameters used in the correlation analysis are summarized in Supplementary Tables 18-20, and the detailed curves are summarized in Supplementary Figs. 44 and 45.

Supplementary Figure 47. (a) TPV, and (b) TA curves under different blend films.

Supplementary Figure 48. Correlation matrix. Correlation of device and photophysics (based on PM6:L8-BO, PM6:D18:L8-BO, PM6:Y6, PM6:D18:Y6, PM7:L8-BO, PM7:D18:L8-BO, PTQ10:L8-BO, and PTQ10:D18:L8-BO). The photovoltaic and photophysical parameters used in the correlation analysis are summarized in Supplementary Table 21, and the detailed curves are summarized in Supplementary Fig. 47.

Supplementary Figure 49. Scatter diagram of photovoltaic ( \(J_{\mathrm{sc}}, \mathrm{FF}\), and PCE) and photophysical ( \(\tau_{\mathrm{c}}, L_{\mathrm{e}}, L_{\mathrm{h}}, \tau_{1}\), and \(\tau_{2}\) ) parameters of binary and ternary devices. On the right are the distribution curves.

\section*{Supplementary Tables}

Supplementary Table 1. Photovoltaic parameters with different PM6:D18 ratios for ternary devices under the illumination of AM \(1.5 \mathrm{G}, 100 \mathrm{~mW} / \mathrm{cm}^{2}\).
\begin{tabular}{ccccc}
\hline PM6:D18:L8-BO & \(V_{\mathrm{oc}}{ }^{\mathrm{a}}(\mathrm{V})\) & \(J_{\mathrm{sc}^{\mathrm{a}}}\left(\mathrm{mA} \mathrm{cm}^{-2}\right)\) & \(\mathrm{FF}^{\mathrm{a}}(\%)\) & \(\mathrm{PCE}^{\mathrm{a}}(\%)\) \\

\section*{Supplementary Notes}

\section*{Supplementary Note 1. Analysis of TPC, TPV, and Mott-Schottky measurements}

The TPV and transient photocurrent (TPC) measurements were used to study the recombination mechanism \({ }^{9}\). The charge density in devices is determined by the differential capacitance method as shown in Supplementary Fig. 26b. A clear exponential dependence on \(V_{\text {oc }}\) is demonstrated. Following \(n=n_{0} e^{\tau / V_{0 c}}\), where \(n_{0}\) is the average charge density in the active layer in dark conditions, the derived charge lifetime versus charge density is shown in Supplementary Fig. 26c. In this case, a power-law dependence indicates that the nongeminate/free charge recombination is the major loss mechanism under open-circuit condition. Fig. 3c shows the relationship between the non-geminate recombination rate coefficient and charge density, and the ternary device exhibits a lower recombination coefficient under the same charge density. Supplementary Fig. 27 shows the defects density of state (DoS) and the built-in potential measured following the Mott-Schottky method \({ }^{10}\). The DoS in the ternary mixture decreases compared to that of PM6:L8-BO blends, yet higher than that of D18:L8BO blends. To further understand the potential role of trap states, impedance spectroscopy (IS) was conducted to access the occupied LUMO DoS, which is a method to probe the density of photo-generated charges \((N)\) as a function of light intensity (or Fermi level) up until 1 sun equivalent condition (shown in Supplementary Fig. 28). The LUMO DoS and related parameters derived from the capacitance spectra are summarized in Fig. 3d and Supplementary Table 11. While no clear difference in terms of \(\delta\) (the energetic disorder parameter), the PM6:D18:L8-BO device shows a larger \(N\) value, correlating well with the \(J_{\text {sc }}\) improvement. Moreover, the device based on D18:L8-BO shows a large \(\beta / \alpha\) (calculated from the slope in Supplementary Fig. 29) of 2.8 indicates more trapped carrier recombination, and the addition of PM6 could suppress this recombination with a smaller \(\beta / \alpha\) of 2.31. A similar conclusion can be drawn from the relative values of estimated trap density ( \(U_{\mathrm{n}, \mathrm{p}}^{\mathrm{Gaa}}\) ) and \(N\), where the PM6:D18:L8-BO device shows the smallest \(U_{\mathrm{n}, \mathrm{p}}^{\mathrm{Gau}} / N\) value (shown in Supplementary Table 11). However, as the ratio between trapped and \(N\) is very small \(\left(<10^{-3}\right)\), trap-assisted recombination is believed to be negligible as opposed to bimolecular recombination in all three devices, which is also evidenced in the slope of SCLC characteristics, \({ }^{11}\) where all three devices show the maximum slope of \(\sim 2\) (see Supplementary Fig. 25).

\section*{Supplementary Note 2. Coupled exciton diffusion, optical transfer matrix, and drift diffusion modelling}

The experimental results have shown that the double fibril network facilitated efficient exciton diffusion and lower recombination are two primary reasons for the improved performance from binary to ternary blends. To further support this claim, we here perform device modelling to quantitatively investigate the effect of exciton diffusion and recombination on electrical and optical response of the photovoltaic devices to the changes of photoactive layer properties. Specifically, the effects of exciton diffusion efficiency and free charge recombination rate constant on \(\mathrm{IQE} / \mathrm{EQE}, J_{\mathrm{sc}}\), and FF are modelled using experimental parameters as inputs. Our simulations start with estimating the exciton diffusion efficiency, followed by optical modelling based on a transfer matrix method, and end by the solution of the charge carrier continuity, transport, and Poisson's equation to account for electrostatic effects.

\section*{Estimating exciton diffusion efficiency with acceptor domains:}

The experimental results show that the exciton decay rate, diffusion length, and domain size are different from blend to blend (Supplementary Table 12). Thus, one would expect a different fraction of excitons to reach the edge of the domains and split to become free charges. To model this process, we imagine the acceptor L8-BO (i.e. the primary absorber domain) to be a simple 3D sphere with a uniform photogeneration profile (see Supplementary Fig. 30). We assume the only loss of excitons within the domain is through direct decay (i.e. through exciton lifetime \(\tau\) ). And the dissociation of excitons is only allowed at the edge or outside of the sphere, with a dissociation rate depending on the blends ( \(k_{\text {diss }}\) ). Note here that in all devices, \(k_{\text {diss }}\) is in the scale of \(\mathrm{ps}^{-1}\), indicating ultrafast dissociation of exciton at donor/acceptor interfaces in all devices, therefore, the key difference here is the size of acceptor domains. The detailed parameters for exciton diffusion modelling are taken from experimental values as summarized in Supplementary Table 12. As such, the exciton diffusion process is governed by the formula below:
\[
0=\nabla D \nabla X(r)+G(r)-\frac{X(r)}{\tau}-k_{\mathrm{diss}}(r) X(r)
\]

Where, \(X(r)\) is the density of exciton as a function of position \((r), D\) is the diffusion coefficient, \(G(r)\) is the exciton generation rate, \(\tau\) is the lifetime of excitons in absence of quencher, and \(k_{\text {diss }}(r)\) is the dissociation rate constant from exciton to free charges. \(k_{\text {diss }}(r)\) is
zero inside and non-zero outside the sphere. The solution of exciton diffusion equation provides the total loss inside the sphere ( \(\iiint \frac{X(r)}{\tau} \mathrm{d} V, \mathrm{~d} V\) is the integral volume), and the exciton diffusion efficiency \(\left(P_{\text {diss }}\right)\) is then calculated via
\[
P_{\mathrm{diss}}=1-\iiint \frac{X(r)}{\tau} \mathrm{d} V / \iiint G(r) \mathrm{d} V
\]

Using the data from Supplementary Table 12 (i.e. diffusion constant, diffusion length, dissociation rate, and phase separation scales), we obtain values of \(P_{\text {diss }}\) by solving exciton diffusion equations. The resulting values are \(93.74 \%, 96.87 \%\), and \(96.64 \%\) for \(\mathrm{D} 18: \mathrm{L} 8-\mathrm{BO}\), PM6:L8-BO, and PM6:D18:L8-BO, respectively. Clearly, PM6:D18:L8-BO and PM6:L8-BO devices show higher exciton diffusion efficiency than D18:L8-BO devices. And no clear difference between PM6:D18:L8-BO and PM6:L8-BO device is seen, which is likely because that i) exciton diffusion in polymer domains is omitted, and ii) variations of exciton diffusion parameters in complex blends cannot be considered in the single domain simulations. We consider the accurate simulation of exciton diffusion process in both polymer and acceptor domains with different sizes is challenging and beyond the scope of this work. Nevertheless, we acknowledge the fact that the difference between PM6:D18:L8-BO and PM6:L8-BO in experimental IQE/EQE is also much smaller than that between PM6:D18:L8-BO and D18:L8-BO, as shown in Supplementary Fig. 7, which to some extent agrees with the simulations results above.

\section*{Calculation of quantum efficiencies, current-voltage characteristics, and fill factor:}

Using the calculated \(P_{\text {diss }}\), we then performed optical and electrical modelling. The optical modelling was conducted using experimental complex refractive index data obtained by ellipsometry measurements. The refractive index data for active layers are shown in Supplementary Fig. 31. The refractive index data of ITO, PEDOT:PSS, and Ag were taken from previously published works \({ }^{12}\), and for simplicity, the transparent interlayer PNDIT-F3N was omitted since it's only 5 nm thick. For drift diffusion modelling, the charge generation rate was calculated using coupled exciton diffusion and optical models. And most of the input parameters were obtained from experimental measurements, except for dielectric constant (set at 3), effective density of state of free charges (set at \(1 \times 10^{26} \mathrm{~m}^{-3}\) ), \({ }^{1}\) and the injection barriers for cathode and anode are set to be close to zero. Since trap-assisted recombination is believed to be negligible in all devices as discussed in the main text, the most important parameter here is then the free-to-free recombination rate coefficient \(\left(B_{\text {dir }}\right)\), i.e. bimolecular recombination
rate coefficient, which follows experimental values obtained using TPV/TPC. The detailed parameters for drift diffusion modelling are shown in Supplementary Table 13.

Supplementary Fig. 32a shows the simulated IQE and EQE using the coupled exciton diffusion, optical and electrical model with AM1.5G solar spectrum. IQE and EQE show a very similar trend as experimental results in Supplementary Fig. 7 when changing the blend, indicating that external parameters, such as reflection and transmission, are not the limiting factors here, agreeing with experimental observations. Moreover, in the wavelength range between 600 and 800 nm , the simulated IQE/EQE of the ternary device is about \(5 \%\) higher than D18:L8-BO device, and the values for PM6:L8-BO device are similar to the ternary device. Overall, the ternary device shows the highest IQE/EQE, which confirms the highest photocurrent. Further current-voltage simulation (Supplementary Fig. 32b) demonstrates the highest \(J_{\mathrm{sc}}\) in the ternary device ( \(\sim 24.6 \mathrm{~mA} \mathrm{~cm}^{-2}\) ), followed by PM6:L8-BO \(\left(\sim 24.0 \mathrm{~mA} \mathrm{~cm}^{-2}\right)\) and D18:L8-BO \(\left(\sim 23.1 \mathrm{~mA} \mathrm{~cm}^{-2}\right)\). Although the exact values do not perfectly match the experimental values of \(J_{\text {sc }}\) in Supplementary Fig. 32b, we note that the trend has been successfully reproduced. The possible reasons for non-perfect match with experiments could be i) exciton diffusion in polymer domains is omitted, and ii) variations of exciton diffusion parameters in complex blends cannot be considered in the single domain simulations. We consider the accurate simulation of exciton diffusion process in both polymer and acceptor domains with different sizes is challenging and beyond the scope of this work.

We further analyzed the fill factors (FFs) using drift diffusion modelling. The calculated FFs reflect well the differences in device parameters, especially the \(B_{\text {dir }}\), where the ternary device again shows the lowest \(B_{\text {dir }}\) experimentally, and correspondingly the highest FF , as shown in Supplementary Fig. 32c. We have also shown in Supplementary Fig. 32c the effect of direct recombination coefficient on FF in the studied devices, a strong connection between FF and \(B_{\text {dir }}\) is observed. The correlation between FF and recombination rate coefficient can also be investigated via a figure-of-merit quantifying the competition between charge recombination and transport, i.e. \(\alpha=\sqrt{\frac{q B_{\mathrm{dir}} L^{3} J_{\mathrm{ph}}}{4 \mu_{\mathrm{e}} \mu_{\mathrm{h}}\left(k_{\mathrm{B}} T\right)^{2}}}\), where \(q\) is the elementary charge, \(k_{\mathrm{B}}\) is the Boltzmann constant, \(L\) is the active layer thickness, \(J_{\mathrm{ph}}\) is the photogenerated current density under 1 sun. \({ }^{6}\) Since the mobilities are rather similar among the three devices, the recombination rate coefficient should be the dominating factor, and the results show that PM6:D18:L8-BO possesses the lowest \(\alpha\) ( 0.76 ), while the values for PM6:L8-BO and D18:L8-BO are 1.02 and 1.74, respectively. The analysis on \(\alpha\) here therefore agrees with the
coupled optical and electrical model results. And the devices studied here lie closely on the border between Shockley-type and transport limited regime following the guideline suggested in reference \({ }^{6}\) (see also Supplementary Fig. 32d).

Overall, the coupled exciton diffusion, transfer matrix, and drift-diffusion model simulations above show decent agreements with our experimental results despite of the simplicity, and further support the claim that enhanced exciton diffusion and reduced free charge recombination are important reasons for the performance enhancement in the ternary device
